Electrochemistry Piero Zanello, Carlo Nervi, Fabrizia Fabrizi de Biani, 2019-05-16 In order to understand the basic aspects of an electrochemical investigation on inorganic molecules in its widest meaning of any molecule which contains at least one metal centre it must be taken into account that in these molecules the metal ligand bonds are of the prevailing covalent type Since electrochemical techniques allow you to add or remove electrons in a controlled manner it is conceivable that the addition or removal of electrons inside these molecules can lead to the formation of new bonds or to the breakage of existing bonds The main aim of this book is to study the effects of such electron addition and removal processes on the molecular frames The second edition of this classic book has been fully revised and updated and is a straightforward logical introduction to electrochemical investigations for inorganic chemists All chapters have been rewritten with new material including the addition of reactivity with nitric oxide to the chapter on the reactivity of metal complexes with small molecules thiolate protected gold nanoclusters has been added to the chapter on metal sulfur and metal carbonyl clusters a new chapter on the digital simulation of electrochemical responses a new chapter on the theoretical calculations to explain the nature of the electrochemical activity of metal complexes new chapters on spectroelectrochemistry and electrochemiluminescence The book covers every aspect of inorganic electrochemistry the introduction is followed by chapters on the basic aspects of electrochemistry followed by practical and applicative aspects and ends with full appendices It is probably the only publication with a simple approach to electrochemical aspects of the topics in inorganic chemistry Bridging the gap between undergraduate and research level electrochemistry books this publication will be a welcome addition to the literature of inorganic chemists It will also be particularly useful to final year students in chemistry and as background reading for graduates and researchers without adequate electrochemical knowledge to become active in the discipline or who want to collaborate with electrochemists Conducting Polymer Electrodes for Thermogalvanic Cells

Kosala Wijeratne, 2019-01-10 Fossil fuels are still the dominant ca 80% energy source in our society A significant fraction is used to generate electricity with a heat engine possessing an efficiency of approximately 35% Therefore about 65% of fossil fuel energy is wasted in heat Other primary heat sources include solar and geothermal energies that can heat up solid and fluids up to 150 C The growing demand and severe environmental impact of energy systems provide an impetus for effective management and harvesting solutions dealing with waste heat A promising way to use waste heat is to directly convert thermal energy into electrical energy by thermoelectric generators TEGs Solid state TEGs are electronic devices that generate electrical power due to the thermo diffusion of electronic charge carriers in the semiconductor upon application of

the thermal field However there is another type of thermoelectric device that has been much less investigated this is the thermogalvanic cell TGCs The TGC is an electrochemical device that consists of the electrolyte solution including a reversible redox couple sandwiched between two electrodes In our study we focus on iron based organometallic molecules in aqueous electrolyte A temperature difference between the electrodes promotes a difference in the electrode potentials Since the electrolyte contains a redox couple acting like electronic shuttle between the two electrodes power can be generated when the two electrodes are submitted to a temperature difference The focus of this thesis is i to investigate the possibility to use conducting polymer electrodes for thermogalvanic cells as an alternative to platinum and carbon based electrodes ii to investigate the role of viscosity of the electrolyte in order to consider polymer electrolytes iii to understand the mechanisms limiting the electrical power output in TGCs and iv to understand the fundamentals of the electron transfer taking place at the interface between the polymer electrode and the redox molecule in the electrolyte These findings provide an essential toolbox for further improvement in conducting polymer thermogalvanic cells and various other emerging electrochemical technologies such as fuel cells redox flow battery dye sensitized solar cells and industrial electrochemical synthesis
