

# Genetic Mapping – Map Distance and frequency of Recombination

Physically, a map unit can be defined as the length of the chromosome in which, on average, one cross-over is formed in every 50 cells undergoing meiosis.

(C) Frequency of recombination:

$$r = \frac{1 + 1}{49 + 49 + 49 + 49 + 1 + 1 + 1 + 1} = \frac{2}{200}$$

= 1 percent = 1 map unit = 1 cM

Genomes: Methods for Genetic and Physical Mapping J.S. Beckmann,T.C. Osborn,2012-12-06 JACQUES S BECKMANN THOMAS C OSBORN Extraordinary progress has been made in the analyses of the genetic structures of higher eukaryotic genomes Only ten years elapsed between the initial proposals to use molecular DNA markers for the generation of a complete linkage map of the human genome 5 17 and the first description of a 10 centimorgan map of one of its chromosomes 22 soon to be followed by others The availability of molecular DNA markers henceforth called genomic markers for a review of their properties see 1 2 20 represents a milestone in genetics by providing the capacity for complete genetic coverage of all genomes It is important to remember that the nature of the DNA polymorphism or of the specific method used to uncover it can be quite different for different marker loci The genetic variation detected can be a result of a simple point mutation a DNA insertion deletion event or a change in repeat copy number at some hypervariable DNA 11 or micro satellite 21 motif Currently the methods of detection can involve use of restriction endonucleases nucleic acid hybridization or DNA sequence amplification Each of these sources of variation and methods of detection can have utility for different applications Furthermore new approaches for the detection of DNA polymorphism are constantly emerging The primary concern here is that the monitored polymorphism defines a genetic marker useful for the desired application

**Genomics Research on Non-Model Plant Pathogens: Delivering Novel Insights into Rust Fungus Biology** Sébastien Duplessis, Guus Bakkeren, David L Joly, 2016-04-14 Fungi of the order Pucciniales cause rust

diseases on many plants including important crops and trees widely used in Agriculture forestry and bioenergy programs these encompass gymnosperms and angiosperms monocots and dicots perennial and annual plant species These fungi are obligate biotrophs and except for a few cases cannot be cultivated outside their hosts in a laboratory For this reason standard functional and molecular genetic approaches to study these pathogens are very challenging and the means to study their biology i e how they infect develop and reproduce on plant hosts are rather limited even though they rank among the most devastating pathogens Among fungal plant pathogens rust fungi display the most complex lifecycles for with up to five different spore forms and for many rust fungi alternate hosts on which sexual and clonal reproduction are achieved The genomics revolution and particularly the application of new generation sequencing technologies have greatly changed the way we now address biological studies and has in particular accelerated and made feasible molecular studies on non model species such as rust fungi The goal of this research topic is to gather articles that present recent advances in the understanding of rust fungus biology their complex lifecycles and obligate biotrophic interactions with their hosts through the means of genomics This includes genome sequencing and or resequencing of isolates RNA Seq or large scale transcriptome analyses genome scale detailed annotation of gene families conformation of genes and or expression of gene complements via proteomics and comparative analyses among the various rust fungi and where feasible with other obligate biotrophs or fungi displaying distinct trophic modes This Research Topic provides a great opportunity to provide an up to date account of rust fungus biology through the lens of genomics including state of the art technologies developed to achieve this knowledge
