Ideals, Varieties, and Algorithms David Cox, John Little, DONAL OSHEA, 2013-03-09 Algebraic Geometry is the study of systems of polynomial equations in one or more variables asking such questions as Does the system have finitely many solutions and if so how can one find them And if there are infinitely many solutions how can they be described and manipulated The solutions of a system of polynomial equations form a geometric object called a variety the corresponding algebraic object is an ideal There is a close relationship between ideals and varieties which reveals the intimate link between algebra and geometry Written at a level appropriate to undergraduates this book covers such topics as the Hilbert Basis Theorem the Nullstellensatz invariant theory projective geometry and dimension theory The algorithms to answer questions such as those posed above are an important part of algebraic geometry This book bases its discussion of algorithms on a generalization of the division algorithm for polynomials in one variable that was only discovered in the 1960's Although the algorithmic roots of algebraic geometry are old the computational aspects were neglected earlier in this century This has changed in recent years and new algorithms coupled with the power of fast computers have led to some interesting applications for example in robotics and in geometric theorem proving In preparing a new edition of Ideals Varieties and Algorithms the authors present an improved proof of the Buchberger Criterion as well as a proof of Bezout's Theorem Appendix C contains a new section on Axiom and an update about Maple Mathematica and REDUCE

**Old and New Aspects in Spectral Geometry** M.-E. Craioveanu, Mircea Puta, Themistocles M. Rassias, 2001-10-31 It is known that to any Riemannian manifold  $M$  with or without boundary one can associate certain fundamental objects Among them are the Laplace Beltrami operator and the Hodge de Rham operators which are natural that is they commute with the isometries of  $M$  elliptic self adjoint second order differential operators acting on the space of real valued smooth functions on  $M$  and the spaces of smooth differential forms on  $M$  respectively If  $M$  is closed the spectrum of each such operator is an infinite divergent sequence of real numbers each eigenvalue being repeated according to its finite

multiplicity Spectral Geometry is concerned with the spectra of these operators also the extent to which these spectra determine the geometry of  $M$  and the topology of  $M$  This problem has been translated by several authors most notably M Kac into the colloquial question Can one hear the shape of a manifold because of its analogy with the wave equation This terminology was inspired from earlier results of H Weyl It is known that the above spectra cannot completely determine either the geometry of  $M$  or the topology of  $M$  For instance there are examples of pairs of closed Riemannian manifolds with the same spectra corresponding to the Laplace Beltrami operators but which differ substantially in their geometry and which are even not homotopically equivalent Calculus and Analytic Geometry Melcher P. Fobes, Ruth B. Smyth, 1963
