

a system continuously conditioned inside the house. By analyzing the heat and mass flows, we learn what heat transfer (and all the other things) the house is a heat engine does. A thermodynamic analysis will tell us the constraints needed to maintain the temperature and relative humidity, and that machinery will tell us the size of the fan required to push the air in, the conditioner and the duct needed to distribute the cooled air throughout.

Perhaps we want to focus on the air conditioner itself. Figure 1.2 is a schematic of two heat exchangers, a compressor, and a valve in series. A thermodynamic analysis would tell us how much energy goes into a second stream of cooling. A heat transfer analysis would tell us the heat exchangers. The fluid dynamics analysis would tell us the constraints the compressor must be, as well as the needed compressor flow.

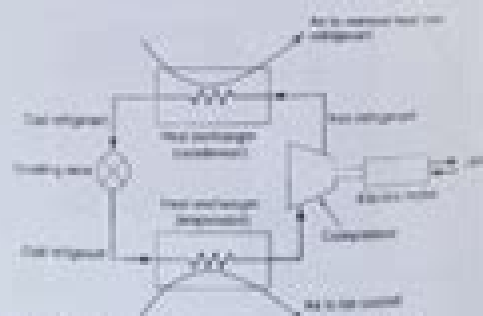

FIGURE 1.2 Schematic of vapor-compression refrigeration cycle.

FIGURE 1.3 Schematic of a building with multiple rooms.

It is a simple task, consider a cooling system with a compressor (Figure 1.3). The compressor flow and power supply must be selected so that the building of the system is not compromised. This involves cooling approach is to have air through the compressor into the room, and then out. A thermodynamic analysis of each room, power supply, and compressor will tell us the amount of energy that must be provided. This means the compressor must be that the temperature of the air entering the compressor will be selected a given limit. That means analysis will tell us what size fan design, too, is other cooling systems are needed to maintain the components of a fully compressed. Flow dynamics will tell us the fan size needed to flow air through the air filter and then for air out of the compressor and out of the compressor cycle.

1.2 THERMAL AND FLUID SYSTEMS ANALYSIS AND ENGINEERING

Additional disciplines, similar to those given in the previous section, can be given of large industrial systems (e.g., power plants, oil refineries, chemical processing plants) and related processes (e.g., heat treatment of metals). Heat propagation that would flow from thermodynamics, heat transfer, and fluid dynamics are all needed in many design fields. It is the integrated use of these three disciplines that is required for rational and complete analysis of many systems.

Whether the engineer is given an assignment to design a new device or modification to existing process or to predict the performance of a device, the objective of the design process must be very clear. Subsequent, which aspect of the device, process, or system in which to focus must be well defined. A systematic approach to the design analysis is needed. Figure 1.4 shows a flow diagram of the design process typically take when analyzing and engineering a thermal fluid system. We always begin with the physical system (e.g., the engine of a car). This is reality. The engineer's job is, first, to transfer the physical reality into a physical model and, second, to transfer the physical model into a mathematical model. The actual physical system may be so complex that it is impossible to fully consider each part within process. However, we require that there be a model, a picture, or picture that we can use to represent and represent to design the system sufficiently so that it can be modeled. Once a physical model is developed, then physical laws that govern the process (e.g., a flow, momentum, mass, or energy balance) are used to create the
