

be central to domain-general processes of reasoning used across a variety of cognitive tasks. If different schemes of representation can provide equivalent performance, then this raises the issues of 1) whether these broader reasoning processes can (or must) also be instantiated with different types of representations, 2) to what extent a single individual may (or must) draw on these different representations for reasoning tasks, and 3) to what degree individual differences may (or must) result from variations in the underlying representations being used.

Our central question is also of immense practical import because the RPM family of tests is used extensively in clinical, educational, vocational, and scientific settings as an accurate assessment of intelligence. Therefore, interpretations of RPM scores should be made only with a thorough understanding of what cognitive implications these scores do and do not provide.

Evidence for Different RPM Strategies

While within- and between-individual differences on the RPM are generally treated as being those of degree and not of type, there is evidence that the use of qualitatively different solution strategies may be responsible for some of these differences. Within-individual differences have been linked to the presence of different problem types on the RPM, i.e. factor analyses and other behavioral markers have suggested that different problems may admit distinct solution strategies (DeShon, Chan, & Weissbein 1995; Dillon, Pohlmann, & Lehman 1981).

Recent studies have highlighted the possibility of there being qualitative differences in RPM solution strategies between individuals with autism and "neurotypical" individuals. Autism is a developmental disorder marked by significant language delay and atypical behaviors in social interaction, communication, and stereotyped or repetitive patterns of behavior and interest (*DSM-IV-TR* 2000). While individuals with autism show impaired performance on many cognitive tasks, many studies report intact or superior performance on certain visuospatial tasks (e.g. Joliffe & Baron-Cohen 1997).

Studies of intelligence tests have shown that, unlike neurotypical individuals who show correlated scores, individuals with autism often demonstrate RPM scores that

are much higher than their Wechsler scores (Mottiron 2004; Dawson et al. 2007). Individuals with Asperger's syndrome show a similar pattern (Hayashi et al. 2008).

One possible explanation for these results is that individuals with autism might be predisposed towards reasoning visually (Kunda & Goel 2008a, 2008b). In this case, they might find the RPM amenable to a visual reasoning solution but the verbal Wechsler subtests very difficult. Recent neuroimaging evidence is consistent with this possibility (Soulères et al. 2009).

Building Computational Accounts of the RPM

Existing computational accounts of problem solving on the RPM, with the exception of Hunt's early work in 1974, use propositional representations and assume that individual differences result from quantitative differences in the problem solving architecture, e.g. number of goals that can be managed, types of shapes that can be discriminated, etc. (e.g. Carpenter, Just, & Shell 1990; Lovén, Forbus, & Usher 2007). In contrast, we are developing three methods for solving RPM problems, each of which uses a fundamentally different representational substrate.

The first is a purely imagistic method that relies on fractal encodings of an RPM matrix. The fractal representations use only grayscale pixel values from an image of an RPM problem and are mathematical abstractions quite rigorously grounded in the theory of fractal image compression (Barnsley & Hurd 1992).

The second method uses a multimodal representation in which elements from an RPM problem are represented using a visuospatial-symbolic scheme, in which the elements can be manipulated symbolically but only with operations based in visual perception, e.g. translation, rotation, scaling, etc. This representation follows the work of Kosslyn, Thompson, and Ganis (2006) on depictive mental representations and is similar to representations used in our earlier work on visual analogy (Davies & Goel 2001; Davies, Goel, & Yaner 2008).

The third method uses propositional representations similar to those in Carpenter, Just, and Shell (1990). We view this chiefly as a control representation with which to compare our first and second methods. We now present our first and second methods in greater detail.

Fractal Representations and the RPM

An RPM problem can be viewed as a sequence of images (ordered in rows and columns), where some unknown transformation T can be said to transform one image into a corresponding adjacent image. In a typical two-by-two RPM problem, there are four such transformations, as shown in Figure 2. (RPM problems can also have three-by-three matrices, which we do not address in this paper.)

RPM problems are formulated to suggest that these transformations are pairwise analogous (i.e. the two row transformations are analogous to one another). We seek to
