is the dramatic Challenger disaster The rubber used to seal the solid rocket booster joints with O rings did not expand at temperatures of 0 C or below resulting in an opening in the solid rocket booster joint through which gas attempted to escape The main physical reason for the heat generation processes is the hysteresis of rubber materials due to deformation and viscoelasticity Most elastomers therefore change significantly over time when exposed to heat and likewise light or oxygen ozone These changes can have a dramatic effect on the life and properties of the elastomers Heat development in a rubber occurs when it is subjected to a variety of compressive stresses in service Heat evolution tests are commonly performed to estimate the quality of use and expected service life of various compounds or material options for end product applications New developments in recent years on test methods in this direction constitute an important part of the book At the same time corresponding simulation and modelling methods have been developed that contribute to a better understanding and enable the predictive simulation of self heating and the kinetics of temperature fields in complex cyclically loaded rubber components Specifically finite strain thermal viscoelastic damage models for predicting the cyclic thermomechanical response of rubber specimens under fatigue are also presented and analytical models for heat diffusion in stressed rubbers
