

Estimation of Machining Time in Facing in a CNC Turning Centre using constant spindle speed and constant cutting velocity

Facing is the machining process of removing metal from the end of a workpiece to produce a flat surface. It is done to create a smooth, flat face perpendicular to the axis of a cylindrical part.

Machining time is the time needed to process or machine a material under some operation(s). The machining time needs to be determined or assessed from time to time for several purposes, such as, assessment of productivity, evaluation of machining cost per piece, determination of man-machine hour cost per piece, assessment of relative performance or capability of any machining methods, machine tool, cutting tool, or any specific techniques in terms of saving in machining time.

The machining time required for a particular operation can be determined either by approximately calculation (estimation) or by actual measurement. Measurement generally provides accurate and precise information but it is tedious and expensive. On the other hand, though estimation by simple calculation may not be accurate, is much more simple, quick and inexpensive. Therefore, machining time is regularly evaluated for different purposes by simple calculation.

Facing of a disc in a CNC turning centre can be done in two cases. One with constant spindle speed and another with constant cutting velocity.

Consider a cylindrical shell with outer diameter d_2 and inner diameter d_1 and other parameters as shown in figure.
