

Echinoderms

Starfish, sand dollars, and sea urchins all belong to a group (phylum) of invertebrates known as echinoderms. The word "echinoderm" means spiny skin, which describes most of the organisms in this phylum. Echinoderms all live in water and are predators or scavengers, the underside of the animal has a mouth and their arms are used to pry open shelled prey such as mollusks.

One of the more unusual aspects of echinoderms is their ability to regenerate lost arms. A starfish that loses an arm can grow a new one if just a couple of weeks. Echinoderms are radially symmetrical, which is obvious from the way their stars (which can vary in number) radiate from the mouth opening.

Echinoderms are usually found in the shallow water near the shore. They spend much of the time resting in the sand or on rocks. Starfish can move using specialized structures called tube feet. Each arm of the starfish has hundreds of tubes with suckers on them to help them navigate over rocks and sand. The suction of the tube feet is powerful enough to open even the most stubborn clam shell. The movement and circulation of a sea star is accomplished by canals within the animal that fill with water, a system called the water vascular system.

Echinoderms do not have a highly developed nervous system, but they do have a nerve ring that surrounds the mouth and helps to coordinate their movements and responses. Sensory cells on their arms gather information about their surroundings, such as light and temperature to help the organism respond to its environment.

Starfish are an important part of shoreline ecosystems. In one experiment, a starfish (*Pisaster ochraceus*) was removed from an area. This starfish was a predator of many mussel species in that location. With the starfish removed, it was thought that the mussels would achieve greater diversity. On the contrary, with the top predator gone, one particular species of mussel came to dominate the community and crowded out all of the other species. In this sense, the starfish is known as a "keystone" species, which is an animal that is important for maintaining a community's biodiversity. A relative of the starfish, the sea urchin, is an important part of kelp communities where sea otters live.

There are several distinct groups of echinoderms related to sea stars (also known as starfish). Sea urchins and sand dollars are grouped together because they have large solid plates that form around their soft bodies. Sea urchins have hundreds of spines sticking off of their bodies, which can serve as a defense against predators. Sand dollars tend to be flat and will spend most of their time submerged under the sand in shallow waters.

Brittle stars are a group of echinoderms found mainly on coral reefs. They have very long flexible arms that can break off (and regenerate later). These broken arms will continue to wiggle and move to distract a predator and allow the organism to escape. Sea cucumbers are odd little creatures that resemble a cucumbers, hence their name. Sea cucumbers usually feed on dead or decaying organic matter on the ocean floor.

Oceans and Human Health Lora Fleming, Lota B. Alcantara Creencia, William H. Gerwick, Hong Ching Goh, Matthew O. Gribble, Bruce Maycock, Helena Solo-Gabriele, 2023-07-14 Oceans and Human Health Opportunities and Impacts Second Edition explores the inextricably interconnected and complex relationship between oceans and humans Through the lens of the expanding oceans and human health meta discipline this work examines the many invaluable ecosystem services offered

by oceans as well as the global anthropogenic impacts and explores the associated risks and benefits to human health. Written and edited by an interdisciplinary team of experts, the book features international perspectives on the resources available to address these benefits and risks, including enhanced research policy and community engagement. The book concludes by examining the future of ocean stewardship and how global populations can unite to nurture and promote our life-enhancing relationship with oceans. This is an indispensable resource for students, researchers, communities, and industry specialists in marine sciences, public health, and international policy. Addresses benefits, opportunities, risks, and impacts resulting from the relationship between oceans and humans, informed by more than 100 international authors. Identifies and links necessary tools to relevant disciplines for action and provides illustrative international case studies. Covers scientific, socioeconomic, political, and ethical analyses behind the latest ocean and human health research. Provides study questions and horizon scans at the end of each chapter to encourage individual thought and action, offering a resource for course instructors, students, and communities.

Biosphere Robert A. Wallace, Jack L. King, Gerald P. Sanders, 1984 *Index to Educational Overhead Transparencies* National Information Center for Educational Media, 1980 Brazilian Coral Reefs Ruy Kenji Papa Kikuchi, Zelinda M. A. N. Leão, Maria Elisabeth de Araújo, Tito M. C. Lotufo, 2024-10-11

The Brazilian coral reefs form structures significantly different from the well-known reef models as follows: they have a growth form of mushroom-shaped coral pinnacles called *chapeirões*; they are built by a low-diversity coral fauna rich in endemic species, with most of them relic forms dating back to the Miocene; and the nearshore bank reefs are surrounded by siliciclastic sediments. The reefs are distributed into four major sectors along the Brazilian coast: the northern, the northeastern, and the eastern regions, and the oceanic islands, but certain isolated coral species can be found in warmer waters in the embayment of the southern region. There are different types of bank reefs: fringing reefs, isolated *chapeirões*, and an atoll present along the Brazilian coast. Corals, milleporids, and coralline algae build the rigid frame of the reefs. The areas in which the major coral reefs occur correspond to regions in which nearby urban centers are experiencing accelerated growth, and tourism development is rapidly increasing. The major human effects on the reef ecosystem are mostly associated with the increased sedimentation due to the removal of the Atlantic rainforest and the disposal of industrial and urban effluents. Fishing resources are seriously declining due to pollution and overfishing, and this reduction impacts artisanal fishers who are impoverished and face food security risks. The effects of warming oceanic waters that have been affecting several reef areas with high-intensity coral bleaching did not show until the 2010 event; episodes of coral mass mortality in Brazilian reefs. However, since 2016, bleaching has increased, as has the mortality of milleporids. There are opportunities to develop purposeful biotechnologies that can support coral reef restoration and conservation. Reciprocally preserved coral reef ecosystems containing peculiar genetic resources allow biotechnological opportunities to provide products and processes for economically and ecologically prosperous societies.
