A new approach for the estimation of body composition: infrared interactance^{1,2}

Juan M Conway, PhD, Karl M Norris, BS, and CE Radwell, PhD

ABSTRACT A new method for the estimation of body composition in humans called infrared interactance, or interactance, infrared interactance is based on the principles of light absorption, reflection, and near-infrared spectroscopy. Body composition (percentage fat) was measured in 20 subjects (10 males and 10 females) by infrared interactance and compared to results from densitometry (dual energy X-ray absorptiometry), skinfold thickness (4- and 7-site measurements), the method of Brix, bioelectrical impedance analysis (BIA), and total body water (TBW) measurements. The method is safe, non-invasive, rapid, easy to use, and may prove useful to estimate percentage body fat, especially in the obese. *J. Nutr.* 124:1105-1110, 1994.

KEY WORDS human body composition, total body water, densitometry measurements, ultrasonic measurements, near-infrared spectroscopy, obesity

Introduction

Interlaboratory comparison of human energy expenditure and other metabolic data depends upon accurate determination of body weight (1), fat-free mass, lean body mass, and/or total body fat (2, 3). A number of methods for measuring fat-free mass, lean body mass, or total body fat exist and include hydrostatic weighing (4, 5), total body potassium determinations (6, 7), deuterium oxide dilution (D₂O) (8, 9), skinfold (SF) (10, 11) or ultrasound (US) (12, 13) measurements, total body electrical conductivity (14-16), and total body impedance (17, 18). We report herein the results of a preliminary study using a new method called interactance (IRI). This method is rapid, safe, non-invasive, and may be useful in research and in clinical and field situations.

Earlier research conducted at the USDA, Beltsville Agricultural Research Center in the area of near-infrared reflectance and transmittance (19-21) has led to the development of the infrared interactance method.

Methods

Twenty adult males and thirty-three adult females were studied (Table 1). They were part of an ongoing

nutrition study at the Beltsville Human Nutrition Research Center. Their weights had been maintained at a state of constant nutrient composition for 12 wk. All were deemed healthy by physical and biochemical evaluations. Written, informed consent was obtained. The research protocol was reviewed and approved by the Human Studies Committee of the USDA Agricultural Research Service, Organismal Sciences, and the University of Maryland, College Park.

Skinfold measurements were made using a computerized ultrasonography model (22), built by Protein Instruments Division of Pacific Scientific, Silver Spring, MD. The measurements were a single beam rapid scanning ultrasonography (linear scan from 500 to 2500 mm) and a five spot probe. The instrument was operated in the transmission mode. Scans were made over the midrange wavelength (700 to 1100 nm). The five spot probe conducted the radiation from the transducer to the selected site on the body and collected the
