PROCESS PARAMETERS OF AL ALLOY CASTINGS PRODUCED BY HIGH PRESSURE DIE CASTING Dharmpal

Deepak, Sulakshna Dwivedi, Nitin Dhawan, 2019-09-16. In the current study, an industrial product electrical wire connector has been casted in cold chamber die casting process using LM2 aluminium alloy to produce certain specimens to be assessed under the study for the determination of the responses: mechanical properties such as impact strength, hardness, and surface roughness. As cold chamber die casting is being popularly known for its efficient and accurate casting process, which can process a broad range of castings with intricate shape easily, hence it requires a lot of study in controlling the process variables with optimum combination of process variables to produce defect-free and sound casting. Therefore, in the current study, the process variables such as pouring temperature (725°C, 750°C, 775°C), intensification pressure (170 kg/cm², 180 kg/cm², 190 kg/cm²), type of coating (oil, graphite, Dycote), graphite coating, and Dycote coating, and type of cooling (air, water, oil) have been varied at three levels, and 9 different experiments have been designed using Taguchi array L9 orthogonal array to assess the effects of different combinations of process variables over the mechanical properties: impact strength, hardness, and surface roughness. The study aims at selecting the optimum combination of process variables on the basis of the responses resulted in the 9 experiments. The graphs for the responses: impact strength, hardness, and surface roughness against each process variable have been plotted and carefully observed to identify the significant process variable along with respective level of operation affecting the respective response. From the overall study, intensification pressure was concluded to be the most significant process variable with maximum contribution to the impact strength and surface finish. The micrograph images captured corresponding to the respective levels of intensification pressure (170 kg/cm², 180 kg/cm², 190 kg/cm²) revealed the presence of shrinkage porosity corresponding to the lowest level of intensification pressure (170 kg/cm²) and with further increase in intensification pressure led to a decrease in the extent of presence of porosity. Dycote coating was considered as the most optimum coating with significant contribution to the

hardness Air cooling and oil cooling were equally significant process variables with equivalent contribution to the mechanical properties **Surface Effects and Contact Mechanics including Tribology XII** J.Th.M. De Hossen,M. Hadfield,C.A.

Brebbia,2015-04-21 The book contains papers from the twelfth in a series of biennial conferences first held in 1993 on the topics of contact mechanics and surface effects and their interaction In general structural components fail by wear corrosion and fatigue that is to say affected and initiated by surface conditions Consequently it is often appropriate to modify the surface layer of a base material or coat it so as to provide an enhanced performance or longer life However in many cases it is the combined effect of wear and corrosion that is damaging contributing to complexity in determining the proper approach The surface treatment chosen should be suitably related to the problem to be solved The necessary thickness of the coating depends largely on the applied loading and environmental conditions The papers in the book address novel protective layers for advances in sliding wear and low friction The contents cover topics such as Experimental and Measurement Tests Surface Modification Surface Problems in Contact Mechanics Thick and Thin Coatings Tribomechanics Computer Simulation
