

PROTEIN SYNTHESIS

TRANSLATION

1. Translation is the process of synthesizing a protein from an mRNA template. The mRNA template is read in groups of three bases called codons. Each codon codes for a specific amino acid.

2. Transfer RNA (tRNA) molecules act as the bridge between the mRNA codons and the amino acids. Each tRNA has an anticodon that is complementary to the mRNA codon. The tRNA also carries a specific amino acid.

3. The ribosome is the site of translation. It moves along the mRNA, reading the codons and adding the corresponding amino acids to the growing polypeptide chain. The process continues until a stop codon is reached, at which point the protein is released.

THE GENETIC CODE

"One codon at a time"

1. Biological systems use sequences of three nucleotides to specify the amino acids that are used to build proteins. These sequences are called codons.

2. Each codon codes for a specific amino acid. There are 64 possible codons, but only 20 different amino acids are used to build proteins. This means that some codons code for the same amino acid.

3. The genetic code is universal, meaning that the same codon codes for the same amino acid in all organisms. This is why we can use the same genetic code to understand the relationship between DNA and proteins in all living things.

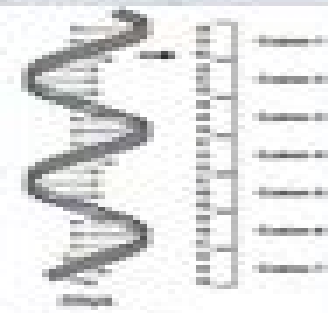

4. The genetic code is a set of rules that determines how the sequence of nucleotides in a DNA or RNA molecule is translated into the sequence of amino acids in a protein.

"One gene - one protein"

1. Each gene contains the instructions for making a specific protein. The sequence of nucleotides in a gene determines the sequence of amino acids in the protein.

2. The protein then performs a specific function in the cell. This is how the genetic code is used to build and maintain the body.

3. A copy of the genetic code can be found on page 119.
