Further genetic studies of some, nonrecombining selfing sites, and their association with recombining sites on the same chromosome suggest different evolutionary histories for the two sets of nuclear markers. This is consistent with the fact that chloroplast markers have not recombined in any examined population. These results and some others indicate that the selfing sites may constitute nonrecombining, and other sites on the same nuclei function as recombining sites in some populations. This suggests that the selfing sites may be located on a different chromosome from the recombining sites. The results suggest that chloroplast markers are located on the same chromosome as the selfing sites.

Further genetic studies are needed, since numerous self-pollinating *Alb.* and *Alba* accessions still contained transgressive or *Alba*-like alleles suggesting allopatric gene exchange. We still need an efficient marker, such as neutral microsatellite alleles, to screen accessions and to identify an *Alb.* *Alba* admixture.
