

If we are to report the results of a measurement as numbers, then either we can produce the measurement, or standardize the method. It would be meaningless if a ruler from another planet were to tell us an object is longer or is “shorter.” If we do not know the meaning of the unit given, then the other hand, if someone hands us with our entire set of measurement reports that a wall is 2 meters high and our unit of length is defined as for 2 meters, we know that the height of the wall is twice our basic length unit. Likewise, if we are told that a person has a mass of 70 kilograms and our unit of mass is defined as for 1 kilogram, then that person is 70 times as massive as our basic unit.¹ Whatever is chosen as a standard must be made as accurate and precise as possible; there can be no measurement reliability—measurements taken by different people in different places must yield the same result.

In 1989, an international committee established a set of standards for length, mass, and other basic quantities. The system established is an abbreviation of the metric system, and is called the **SI system** of units. (The abbreviation SI comes from the system’s French name “Système International.”) In this system, the units of length, mass, and time are the meter, kilogram, and second, respectively. Other SI standards established by the committee are those for temperature (the kelvin), electric current (the ampere), luminous intensity (the candela), and the amount of substance (the mole). In our study of mechanics we shall be concerned only with the units of length, mass, and time.

Length

In 1790, the king of England decreed that the standard of length in his country would be based on the foot and would be precisely equal to the distance from the tip of his nose to the end of his outstretched arm. Naturally, the original standard for the foot adopted by the French was the length of the nose from King Louis XVI. This standard prevailed until 1790, when the legal standard of length in France became the meter defined as one ten-millionth the distance from the equator to the North Pole along one particular longitudinal line that passes through Paris.

Many other systems for measuring length have been developed over the years, but the advantages of the French system have caused it to prevail in almost all countries and in scientific circles worldwide. As accurate as 1790, the length of the meter was defined as the distance between two lines on a specific platinum-iridium bar stored under controlled conditions in France. This standard was then chosen for several reasons, a principal one being that the French accuracy with which the separation between the lines on the bar was far surpassed those on even the most sophisticated of scales and calipers. In the 1960s and 1970s, the meter was defined as 1/100 000 000 wavelengths of orange-red light emitted from a krypton-86 lamp. Moreover, in October 1983, the **meter (m) was redefined as the distance traveled by light in vacuum during a time of 1/299 792 458 second**. In effect, this latest definition establishes that the speed of light in vacuum is precisely 299 792 458 m per second.

Table 2.1 lists approximate values of some measured lengths.

¹ “The need for carrying numerical values to indicate measured physical quantities was suggested by Simon Stevin (1580–1649), Giovanni Galilei (1564–1642), and others who were observing that one can speak of things, objects, and regions in the universe, one should have something other to their other side, namely, a given or a condition, some knowledge or of a larger and smaller size. It was for the beginning of knowledge that one has already to use thought abstracted to the state of nature.”
