

If we are to report the results of a measurement as accurate as we believe we can produce this measurement, a standard must be defined. It would be meaningless if a ruler from another planet were to tell us an object is longer or is “shorter.” If we do not know the meaning of the unit length, then the ruler itself, if someone built one with our system of measurement reports that it will be 2 meters long, and our unit of length is defined as for 2 meters, we know that the length of the unit is twice our basic length unit. Likewise, if we are told that a person has a mass of 70 kilograms and our unit of mass is defined as for 1 kilogram, then that person is 70 times as massive as our basic unit.¹ Whatever is chosen as a standard must be made as accurate and precise as we possibly can for measurement reliability—measurements taken by different people in different places must yield the same result.

In 1980, an international committee established a set of standards for length, mass, and other basic quantities. The system established is an abbreviation of the metric system, and it is called the **SI system** of units. (The abbreviation SI comes from the system’s French name “Système International.”) In this system, the units of length, mass, and time are the meter, kilogram, and second, respectively. Other SI standards established by the committee are those for temperature (the kelvin), electric current (the ampere), luminous intensity (the candela), and the amount of substance (the mole). In our study of mechanics we shall be concerned only with the units of length, mass, and time.

Length

In 1790 the king of England decreed that the standard of length in his country would be based on the foot and would be precisely equal to the distance from the tip of his nose to the end of his outstretched arm. Naturally, the original standard for the foot adopted by the French was the length of the nose from of King Louis XVI. This standard prevailed until 1790, when the legal standard of length in France became the meter defined as one ten-millionth the distance from the equator to the North Pole along one particular longitudinal line that passes through Paris.

Many other systems for measuring length have been developed over the years, but the advantages of the French system have caused it to prevail in almost all countries and in scientific circles worldwide. As accurate as 1980, the length of the meter was defined as the distance between two lines on a specific platinum-iridium bar stored under controlled conditions in France. This standard was then chosen for several reasons, a principal one being that the fastest accuracy with which the separation between the lines on the bar can be determined does not even the various imperfections of science and technology. In the 1960s and 1970s, the meter was defined as 1 650 763.73 wavelengths of orange-red light emitted from a krypton-86 lamp. Moreover, in October 1983, the **meter (m) was redefined as the distance traveled by light in vacuum during a time of $1/299\,792\,458$ second**. In effect, this latest definition establishes that the speed of light in vacuum is precisely $299\,792\,458$ m per second.

Table 2.1 lists approximate values of some measured lengths.

¹ The word for carrying numerical values to indicate measured physical quantities was suggested by Simon Stevin (1580–1647), a French mathematician. “I believe we have often seen our doctors when they are speaking about illness and injuries in the hospitals, use words like ‘something about 15,’ their others use ‘around 100,’ and so on, and I have heard that the words ‘about’ and ‘around’ are used by the beginning of knowledge that you have already in your thoughts attached to the state of nature.”
