Partitioned convolution algorithms for real-time auralization Frank Wefers, 2015-05-11 This work discusses methods for efficient audio processing with finite impulse response FIR filters Such filters are widely used for high quality acoustic signal processing e g for headphone or loudspeaker equalization in binaural synthesis in spatial sound reproduction techniques and for the auralization of reverberant environments This work focuses on real time applications where the audio processing is subject to minimal delays latencies Different fast convolution concepts transform based interpolation based and number theoretic which are used to implement FIR filters efficiently are examined regarding their applicability in real time These fast elementary techniques can be further improved by the concept of partitioned convolution This work introduces a classification and a general framework for partitioned convolution algorithms and analyzes the algorithmic classes which are relevant for real time filtering Elementary concepts which do not partition the filter impulse

response e.g regular Overlap Add and Overlap Save convolution and advanced techniques which partition filters uniformly and non uniformly The algorithms are thereby regarded in their analytic complexity their performance on target hardware the optimal choice of parameters assemblies of multiple filters multi channel processing and the exchange of filter impulse responses without audible artifacts Suitable convolution techniques are identified for different types of audio applications ranging from resource aware auralizations on mobile devices to extensive room acoustics audio rendering using dedicated multi processor systems
