*Photoreceptor Optics* A.W. Snyder, R. Menzel, 2012-12-06 The above consideration indicates that at present many of the experimental facts on PS in animals can be quantitatively explained within the limits of the universal photoreceptor membrane concept Of course existence of preferential orientation of the absorbing dipoles in the tubuli of the rhabdomeres can not be totally rejected We hope that the concept of the universal photoreceptor membrane may serve as the useful instrument when dealing with newly discovered properties of visual cells so that true mechanisms of electrical and optical coupling will be searched for instead of assumptions being made on additional properties of the photoreceptor membrane in every new animal under study 5 Absorption Spectrum of the Universal Photoreceptor Membrane and Spectral Sensitivity of the Photoreceptor 5 1 Preliminary Notes It seems nearly self evident that the absorption spectrum of the photoreceptor membrane coincides exactly with that of the visual pigment it contains Hence the membrane must exhibit three bands of absorption the principal band with its peak within the limits of visible spectrum or a peak the secondary band between 340 and 380 nm S peak and the third protein band in the ultraviolet UV at 280 nm COLLINS et al 1952 The main peak of absorption is located within the range 433 575 nm for retinol based pigments and between 438 and 620 nm for 3 dehydroretinol based pigments the position of Amax depending on many ecological factors **Introducing Grammar**
