Darwin's Finches Lab

In this laboratory students will explore how changes in a trait can affect the survivability of an organism. Students will also explore how changes in a trait can have long term consequences for a species over multiple generations.

Background:

When the naturalist, Charles Darwin went on the expedition with the HMS Beagle he encountered an interesting situation with the finches on the Galapagos Islands. On the various islands in the region the finches there had different beak shapes and sizes from each other and the finches on the mainland of South America. Darwin was puzzled by this and wondered what had caused the changes amongst these finches. After more study, Darwin realized that the finches had different beaks because of the food that was available to them on their own island.

Darwin determined that differences in food sources had, over many generations, changed the population of finches to prefer certain beak shapes and sizes to help them survive. This is in essence what natural selection is. Animal traits are "selected" due to the natural surroundings individual organisms find themselves in. The individuals with the best traits survive the longest and are able to pass on their traits to their offspring. Therefore in the next generation more individuals have the desired trait. Eventually, the desired trait becomes the only one exhibited in that group and a new species can form.

Naturally selected traits can be chosen within only a few generations, depending on the selective pressures involved. In this lab students will see that after just a few generations one particular trait can come to dominate a community if it is better suited for a task like eating.
