neurologic disease and of treatment effects beyond the description of changes on the standard neurologic examination is a relatively recent development. Controlled clinical trials and outcomes research are at the heart of modern information based medicine and neurologic scales are essential tools in clinical trials designed to provide this information. A Resource for Clinical Trials The Handbook of Neurologic Rating Scales provides a resource for clinicians and clinical investigators in the broad field of neurology and neurologic rehabilitation to help them evaluate the clinical trials literature by providing information on the scales being used, evaluate and select appropriate and efficient scales for clinical trials and outcomes research and provide information that will help them to develop new scales or measures or to improve existing ones. A Resource for Evaluating Disease Status Outcomes research is playing an increasingly important role in clinical management and neurorehabilitation and these also depend largely on measurement of disease status and change. In this era of managed care neurologists must produce outcomes data demonstrating the effectiveness of neurologic care if the specialty is to survive and certainly if it is to thrive. Even effective therapies are likely to fall by the wayside if studies to prove their effectiveness are not done. Comprehensive and Standardized Information on All Scales Each chapter in this volume contains the scales of importance and in current use including a sequence of scale descriptions and specific scales in a standard format as well as a summary and recommendations indicating which scales are most useful for specific purposes and whether a combination of scales is particularly useful or if better scales are needed. Each entry notes the purpose for which the scale was developed and its current uses if they differ from those for which it was developed, a detailed description of the scale, information about validation such as Does the scale have face validity i.e. does it appear to measure what it purports to measure, how and by whom the scale is administered, the time needed to administer and score the scale, the scale itself or when the scale is proprietary or too long for inclusion, a description and key references, special considerations including unusual measures needed to obtain a valid score or problems in administering the test in specific patients, advantages or what makes the scale good or useful, Disadvantages or what makes the scale difficult to use or impairs its reliability, key references including the original publication of the scale and its validation. Downloadable PDFs of the scales contained in the Handbook of Neurologic Rating Scales are included with the purchase of this book. The password to download the files can be found in the book itself.

Examiner Consistency of Assigning Manual Muscle Testing Grades Michelle

Menard, Gretchen Peterson, Elizabeth Spadafora, Kerry Spinale, 1998. **Abstract BACKGROUND AND PURPOSE** Manual muscle testing is the most commonly used procedure to assess patient strength. The purpose of this study was to determine the consistency in which physical therapists assign manual muscle testing grades. **SUBJECTS** The subjects were 38 volunteer physical therapists from various clinical settings. All subjects had at least two years of clinical experience. **METHODS AND MATERIALS** Subjects were instructed to apply either minimum, moderate or maximum pressure which corresponded to assigning a grade of fair plus, good or normal according to the Kendall system respectively. The pressure was applied through

the Nicholas Manual Muscle Tester to the right hip flexor muscle group of the researcher A retest was performed approximately two weeks following the initial test

STATISTICAL ANALYSES The absolute value of the difference between the initial test and retest was used to compare consistency of each subject Paired samples t tests were used to test for differences from the initial test to retest for each force level A 2 X 3 repeated measures analysis of variance ANOVA was used to compare force means among force levels and between test days The standard error of the measure SEM was calculated to estimate the precision of measurement made by examiners at each force level and test day

RESULTS No significant difference was found between the initial test and retest for any of the force levels Inconsistencies were found between the initial test and retest for each subject at each force level Inconsistencies in the amount of applied pressure were found between subjects at each force level Subjects were found to be the most inconsistent when applying maximum pressure

CONCLUSION Clinicians were unable to reproduce the same force from initial test to retest Clinicians also varied in the amount of pressure they perceived as minimum moderate and maximum

RELEVANCE Inconsistencies in assigning grades exist therefore manual muscle testing may not be the most clinically useful measurement of strength

Daniels and Worthingham's Muscle Testing - E-Book Dale Avers, Donovan J.
