Charles Darwin visited the Galapagos Islands in 1835. Darwin saw birds that he thought were blackbirds, wrens, and mockingbirds. Later Darwin found that they were actually all the same type of bird. He called these birds the Galapagos Finches. Thirteen different species of finches live on the Galapagos Islands. Scientists think these finches came from a single ancestor, a finch that lived on the ground and ate seeds.

These finches have developed very different beaks depending on the type of food available on each of the islands. Finches that eat seeds have large crushing beaks made to crack the shells of seeds. Other finches have developed beaks for drilling holes in wood, eating cactus or even drinking the blood of other birds.

QUESTION 44

In 1983, large-beaked finches arrived in the Galapagos. These finches eat large seeds because their beaks are too big to eat small seeds. They forced finches with smaller beaks to rely on the small seeds for food. In 2003, a drought killed most of the plants with large seeds that the larger finches ate. The most likely effect of this event was that the finches with larger beaks

- (A) used the smaller finches as a food source.
- (B) were unable to eat and died out.
- (C) started eating the smaller seeds.
- (D) were able to survive and repopulate.
