Continuous Models for Cameras and Inertial Sensors Hannes Ovrén,2018-07-25 Using images to reconstruct the world in three dimensions is a classical computer vision task Some examples of applications where this is useful are autonomous mapping and navigation urban planning and special effects in movies One common approach to 3D reconstruction is structure from motion where a scene is imaged multiple times from different positions e g by moving the camera However in a twist of irony many structure from motion methods work best when the camera is stationary while the image is captured This is because the motion of the camera can cause distortions in the image that lead to worse image measurements and thus a worse reconstruction One such distortion common to all cameras is motion blur while another is connected to the use of an electronic rolling shutter Instead of capturing all pixels of the image at once a camera with a rolling shutter captures the image row by row If the camera is moving while the image is captured the rolling shutter causes non rigid distortions in the image that unless handled can severely impact the reconstruction quality This thesis studies methods to robustly perform 3D reconstruction in the case of a moving camera To do so the proposed methods make use of an inertial measurement unit IMU The IMU measures the angular velocities and linear accelerations of the camera and these can be used to estimate the trajectory of the camera over time Knowledge of the camera motion can then be used to correct for the distortions caused by the rolling shutter Another benefit of an IMU is that it can provide measurements also in situations when a camera can not e g because of excessive motion blur or absence of scene structure To use a camera together with an IMU the camera IMU system must be jointly calibrated The relationship between their respective coordinate frames need to be established and their timings need to be synchronized This thesis shows how to automatically perform this calibration and synchronization without requiring e g calibration objects or special motion patterns In standard structure from motion the camera trajectory is modeled as discrete poses with one pose per image Switching instead to a formulation with a continuous time camera trajectory provides a natural way to handle rolling shutter distortions and also to incorporate inertial measurements To model the continuous time trajectory many authors have used splines The ability for a spline based trajectory to model the real motion depends on the density of its spline knots Choosing a too smooth spline results in approximation errors This thesis proposes a method to estimate the spline approximation error and use it to better balance camera and IMU measurements when used in a sensor fusion framework Also proposed is a way to automatically decide how dense the spline needs to be to achieve a good reconstruction Another approach to reconstruct a 3D scene is to use a camera that directly measures depth Some depth cameras like the well known Microsoft Kinect are susceptible to the same rolling shutter effects as normal cameras This thesis quantifies the effect of the rolling shutter distortion on 3D reconstruction depending on the amount of motion It is also shown that a better 3D model is obtained if the depth images are corrected using inertial measurements Att anv nda bilder f r att terskapa v rlden omkring oss i tre dimensioner r ett klassiskt problem inom

mobility of the solution usability issues etc Practical considerations dictate that there is not a one size fits all solution to the variety of interaction scenarios however there are principles and methodological approaches common to a wide range of problems in the domain While new sensors such as the Microsoft Kinect are having a major influence on the research and practice of vision based interaction in various settings they are just a starting point for continued progress in the area In this book we discuss the landscape of history opportunities and challenges in this area of vision based interaction we review the state of the art and seminal works in detecting and recognizing the human body and its components we explore both static and dynamic approaches to looking at people vision problems and we place the computer vision work in the context of other modalities and multimodal applications Readers should gain a thorough understanding of current and future possibilities of computer vision technologies in the context of human computer interaction **Technological Advances in Rehabilitation, An Issue of Physical Medicine and Rehabilitation Clinics of North America** Joel Stein,2019-04-15 Guest edited by Drs Joel Stein and Leroy R Lindsay this issue of Physical Medicine and Rehabilitation Clinics will cover several key areas of interest related to Technological Advances in Rehabilitation This issue is one of four selected each year by our series Consulting Editor Dr Santos Martinez of the Campbell Clinic Articles in this issue include but are not limited to Functional Electrical Stimulation Non Invasive Brain Stimulation Spinal Cord Stimulation for Motor Rehabilitation Robotics for Limb Rehabilitation Virtual Reality and Gaming New Technologies in Prosthetics and Amputee Rehabilitation Regenerative Medicine Smart Homes and other Technology for Adaptive Living Big Data and Rehabilitation and Telemedicine in Rehabilitation <u>Computer Vision and Machine Learning with RGB-D Sensors</u> Ling Shao,Jungong Han,Pushmeet Kohli,Zhengyou Zhang,2014-07-14 This book presents an interdisciplinary selection of cutting edge research on RGB D based computer vision Features discusses the calibration of color and depth cameras the reduction of noise on depth maps and methods for capturing human performance in 3D reviews a selection of applications which use RGB D information to reconstruct human figures evaluate energy consumption and obtain accurate action classification presents an approach for 3D object retrieval and for the reconstruction of gas flow from multiple Kinect cameras describes an RGB D computer vision system designed to assist the visually impaired and another for smart environment sensing to assist elderly and disabled people examines the effective features that characterize static hand poses and introduces a unified framework to enforce both temporal and spatial constraints for hand parsing proposes a new classifier architecture for real time hand pose recognition and a novel hand segmentation and gesture recognition system <u>Human Movement and Motor Control in the Natural Environment</u> Peter A Federolf,Maurice Mohr,Thorsten Stein,Gert-Jan Pepping,Steven van Andel,Gillian Weir,2023-06-08 The basic understanding of human movement and control of human movement stems largely from laboratory measurements where human movement can be quantified with high precision and accuracy but where the artificial environment compromises ecological validity A good example for this issue was demonstrated in a recent

investigation specifically that the walking gait pattern of healthy individuals in a laboratory changed as a function of how many researchers were present during the experiment Observations like these underscore that study volunteers adapt their behavior to the specific laboratory environment and warrant the question of how well we can transfer our lab based understanding of gait patterns and the underlying neuromuscular control system to walking during daily living Another research area where lab based movement assessments have led to conflicting findings is the field of sports injury prevention Many neuromuscular training programs have been shown to be effective in reducing the sport injury rate in athletes by 30 50% or more in a variety of different multi directional sports Nevertheless lab based assessments of the same athletes who completed those training programs were often not able to detect improvements in motor control of sport specific movements or a reduction in joint loading two factors thought to be closely linked with sport injury risk This disconnect suggests that lab based assessments of movement and motor control are often poor indicators of player behavior during real game scenarios and may limit our ability to screen athletes for injury risk or monitor their progress in rehabilitation These examples highlight that we should strive for the assessment and investigation of human movement and motor control in natural environments i e where individuals patients athletes or other groups of interest perform explore and interact under real world conditions
