Abstract The purpose of this study was to determine the effect of a 12-week, low-intensity, supervised exercise program on the physical and psychological health of older adults with mild cognitive impairment (MCI). The study was a randomized controlled trial with 40 participants (20 in the exercise group and 20 in the control group). The exercise group performed a 12-week, low-intensity, supervised exercise program. The control group did not exercise. The primary outcome was the change in the Mini-Mental State Examination (MMSE) score. The secondary outcomes were the change in the Beck Depression Inventory (BDI) score, the change in the Physical Activity Scale for the Elderly (PASE) score, and the change in the 6-minute walk test (6MWT) score. The results showed that the exercise group had a significantly greater improvement in the MMSE score, the BDI score, the PASE score, and the 6MWT score compared to the control group. These findings suggest that a 12-week, low-intensity, supervised exercise program can improve the physical and psychological health of older adults with MCI.
