

Section 1: The Science of Light

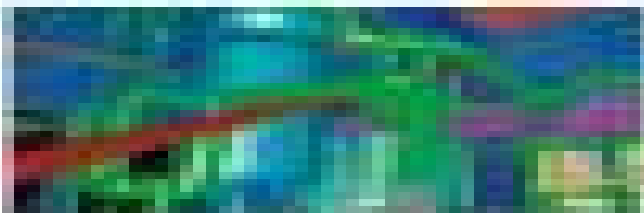

Figure 1: Dispersion of white light by a glass prism.

Figure 2: A natural rainbow showing the dispersion of light.

Light is a form of energy that travels in waves. It is visible to the human eye and is essential for life on Earth. Light can be described by its wavelength, frequency, and speed.

The speed of light in a vacuum is approximately 3×10^8 meters per second. This speed is constant for all wavelengths of light. However, the speed of light changes when it passes through a medium, such as water or glass. This change in speed is what causes the refraction of light.

Refraction is the bending of light as it passes from one medium to another. The amount of bending depends on the refractive index of the two media. The refractive index is a measure of how much the speed of light is reduced when it enters a medium. The refractive index of water is approximately 1.33, and the refractive index of glass is approximately 1.5.

Dispersion is the separation of light into its constituent colors. This occurs because different colors of light have different wavelengths and therefore different refractive indices. When white light passes through a prism, the different colors are refracted by different amounts, causing them to separate.

The spectrum of light is the range of colors that can be seen by the human eye. It is a continuous spectrum, meaning that there are no gaps between the colors. The colors of the spectrum are red, orange, yellow, green, blue, and violet.
