

Example : To find the fundamental crystal frequency for an r. f. input of 83.666 Mc/s :

- 1) Consulting Table 2.4, it can be seen that this r. f. falls within range 4 and the harmonic factor is therefore 2.

$$\text{Crystal frequency} = \frac{83.666 + 1.5}{2} = 42.583 \text{ Mc/s}$$

A $\pm 10\%$ tolerance is permitted on the 1.5 Mc/s i. f. (± 150 kc/s) and, since the normal tolerance on crystal frequency for $+20^{\circ}\text{C}$ to $+60^{\circ}\text{C}$ temperature operation is $\pm 0.01\%$, a crystal with a frequency of 42.58 Mc/s and normal tolerance should be suitable and it is not usually necessary to specify a tighter tolerance.

Note : Where i. m. deviation approaches the full i. f. bandwidth and the r. f. approaches 1000 Mc/s, the crystal tolerance should be as close as possible for minimum distortion and crystals with tighter frequency limits ($\pm 0.003\%$) should be specified.

In every case the crystal frequency selected should be such that the lowest possible harmonic factor gives the required operating frequency. This is automatically given by Table 2.4 using the procedure described.

Example : Required oscillator frequency is 176 Mc/s.

- 1) It can be seen that a crystal of 22 Mc/s operating with a harmonic factor of 8 will satisfy frequency conditions.
- 2) However, a crystal of 44 Mc/s operating with a harmonic factor of 4 should be specified for maximum output from the oscillator.

Crystals are fully specified in Data Sheet QO1670F, to which reference should be made for further details if required. Both data sheet and crystals are available from The Marconi Co. Ltd., Chelmsford, Essex.

2.16 F.M. STEREO MEASUREMENTS

Distortion and channel separation in stereo systems which are designed to meet U. S. Federal Communications Commission (F. C. C.) requirements can be measured with the TF 2300 Modulation Meter. The general procedures are described in the following sections.

2.16.1 Harmonic distortion

It can be assumed that distortion introduced by the modulation meter is small in comparison with that in stereo transmitters, being typically better than 0.2% for deviations up to ± 75 kc/s and therefore, for practical purposes, can be ignored.

The typical frequency spectrum of a G. E. - Zenith type of f. m. stereo signal when a 1 kc/s test tone (for example) is applied to the left channel and no signal to the right, is shown in Fig. 2.5.

Ideally, only the fundamental 1 kc/s signal in the left + right (L + R) channel and the 37 and 39 kc/s sidebands of the suppressed sub-carrier in the L - R channel should be present. In practice, however, harmonic distortions will occur at 2, 3, 4 kc/s ... in the L + R channel and at 37 and 39, 36 and 40, 35 and 41 kc/s ... in the L - R channel. These are the distortion components which it is desired to measure.
