

C) Emulsifying agent assists in the formation of emulsion by forming following interfacial films

- a) Formation of rigid interfacial film (mechanical barrier of coalescence)
- b) Formation of electrical double layer – (electrical barrier to approach of particles)

a) The dispersed globules are known to acquire an electric charge during the process of emulsification. The globules gather two charged layers around themselves called Helmholtz double layer. The electrical double layer consists of stern layer i.e. the layer of charged ions on the surface and the diffuse layer consisting of charged ions distributed upto varying distances around stern layer. The potential produced by the double layer creates a repulsive effect between the oil droplets and thus hinder coalescence.

b) The surface active agents tend to concentrate at interfaces and the emulsifiers are adsorbed at oil – water interfaces as monomolecular films. If the concentration of the emulsifier is high enough, it forms a rigid film between the immiscible phases which acts as a mechanical barrier to both adhesion & coalescence of emulsion droplets.
