Hormonal Control of Metamorphosis

In amphibians, thyroid hormones, thyroxine (T₄) and triiodothyronine (T₃), regulate the rate at which metamorphosis occurs. Metamorphosis is the change that takes place during the development of a postembryonic form, such as a tadpole, into an adult.

Different species of salamanders show variations in metamorphosis (Figure 2). Some salamanders do not metamorphose, retaining the larval characteristics, such as tail and gills, their entire life. They do, however, reach sexual maturity and reproduce—a characteristic of adults.

Figure 2
Metamorphosis in a salamander

The variations of 3 species of salamanders are shown in Table 3.

Table 3

Type of salamander	Description of metamorphosis
mud puppy (<i>Necturus</i>)	no metamorphosis
Mexican salamander (<i>Ambystoma mexicanum</i>)	no metamorphosis
tiger salamander (<i>Ambystoma tigrinum</i>)	metamorphosis in most habitats, except glacial lakes

Hypothesis

In an attempt to collect more information about these variations in the metamorphosis of salamanders, an examination was conducted, which revealed that all three species have thyroid glands. There are several hypotheses that could be tested to explain why the mud puppy and Mexican salamander do not metamorphose:

- The thyroid glands do not produce enough T₃ or T₄ for metamorphosis to occur in these salamanders.
- The environment does not contain enough iodine for the T₃ or T₄ to be formed.
- The pituitary does not produce enough thyroid-stimulating hormone (TSH).
- The amphibians lack some other substance that is necessary for metamorphosis.

The following experiments were carried out to test these hypotheses.

Procedure I

1. Various concentrations of T₃ and T₄ were given to a large number of different species of *Necturus*.

Observation

No metamorphosis occurred in any of the salamanders.

- (a) Would it have helped at this point to administer either TSH or TRH? Explain.

Procedure II

2. Fifty young frog tadpoles were divided into two equal groups. Group A was given an extract from the pituitary glands of the mud puppy. Group B acted as a control, receiving no extract from the pituitary.

Slama,M. Romanuk,F. Sorm,2012-12-06 The application of organic insecticides in the

agrotechnical praxis resulted in a great and unexpected progress in the control of insect pests and was of a great economical value all over the world. The widespread application of these agents however is also accompanied by negative effects. The principal drawback of classical insecticides consists in the lack of their specificity, the useful insects being killed together with insect pests. Furthermore, the broad scale application for many years led to the formation of more resistant insect strains requiring higher and higher doses of insecticides. The residues of the mostly used chlorinated compounds accumulate in human and animal foods producing directly or indirectly harmful effects in human subjects. The critical situation led in many developed countries to the restriction in the usage of some types of classical insecticides. Under these circumstances it is quite natural that novel routes for the control of insect pests are investigated. In this connection attention has been paid especially to the insect endocrinology and insect hormones which regulate the admirable and in many regards specific development from the egg to the adult insect. The recent successful discoveries in this field are thus in close relation to the practical requirements. Isolation and identification of moulting hormones and juvenile hormone like naturally occurring substances not only made possible an exact investigation of their physiological effects but also stimulated the chemical research.
