Describe how the embryos changed for each of these organisms from their earliest to latest stages.

Species	Anatomical Changes From Early to Late Stages
Human	Developed limbs, defined features in face, neck, ears, loss of tail, tiny fingers present
Chicken	Developed beak, tail shorter, wings and legs developed, head quite large
Rabbit	Tail gone, developed limbs, detailed features in ears and mouth
Tortoise	Shell developed, limbs have developed, tail is thinner, large belly, long tail, beak
Salamander	Has gills, tail and large underbelly
Fish	fins developed, gills, tail and scales

1. Look again at the six embryos in their earliest stages. Describe the patterns you see. What physical similarities exist between each of the embryos?

Same basic shape, circular spots (eyes) and underbelly, all have tails, tiny bumps on underside, hole for ear

2. Does this suggest an evolutionary relationship? Explain how these embryos can be used as evidence of a common ancestor between each of these six organisms.

Examination of vertebrate embryos reveals that during corresponding stages of early development, the embryos appear to be very similar. For example, all vertebrate embryos pass through stages in which they have gill pouches. The pouches eventually develop into the gill apparatus in fish; in later-evolving vertebrates that do not have gills, the gill pouches undergo further refinement and develop into structures associated with the head and neck. Similarly, all early vertebrate embryos have tails, which persist in some animals but regress during the later stages of development of humans. Thus, the individual development of an animal occurs through a series of stages that paint a broad picture of the evolutionary stages (phylogeny) of the species to which it belongs.
