Writing the Statistical Report: Part 1: Statistical Analysis of Experimental Data

After completing the experiment, you will have data representing the results of the experiment. The first step in the analysis is to organize the data into a table. The table should have columns for the independent variable (the factor that is being manipulated) and the dependent variable (the factor that is being measured). The table should also have rows for each experimental condition (the different levels of the independent variable).

The next step in the analysis is to calculate the mean and standard deviation for each experimental condition. The mean is the average of the data points, and the standard deviation is a measure of the spread of the data. The mean and standard deviation can be calculated using the following formulas:

$$\text{Mean} = \frac{\sum x}{n}$$

$$\text{Standard Deviation} = \sqrt{\frac{\sum (x - \text{Mean})^2}{n}}$$

where x is the value of the dependent variable, n is the number of data points, and \sum is the sum of the values.

The next step in the analysis is to calculate the t-value. The t-value is a measure of the difference between the means of two experimental conditions. The t-value can be calculated using the following formula:

$$t = \frac{\text{Mean}_1 - \text{Mean}_2}{\sqrt{\frac{s^2}{n}}}$$

where Mean_1 and Mean_2 are the means of the two experimental conditions, s^2 is the variance of the data, and n is the number of data points. The t-value can be compared to a critical value from a t-distribution table to determine if the difference between the means is statistically significant.
