

- drainage basin** is the area of land around the river that is drained by the river and its tributaries.
- interfluve** - the area of high land forming the edge of a river basin
 - Source** - where a river begins
 - Mouth** - where a river meets the sea
 - Confluence** - the point at which two rivers meet
 - Tributary** - a small river or stream that joins a larger river
 - Channel** - this is where the river flows

Erosion

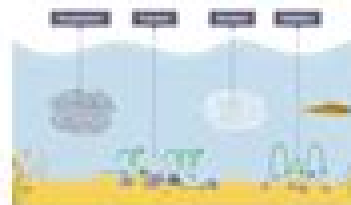

- Erosion** is the process that wears away the river bed and banks. Erosion also breaks up the rocks that are carried by the river.
- Hydraulic action** - This is the direct power of the water as it smashes against the river banks. Air becomes trapped in the cracks of the river bank and bed, and causes the rock to break apart.
 - Attrition** - When pebbles grind along the river bank and bed in a sandpapering effect.
 - Corrosion** - Corrosion makes the river is carving trough against each other. They break apart to become smaller and more rounded.
 - Solution** - When the water dissolves certain types of rocks, e.g. limestone.

- A long profile** is a line representing the river from its source where it starts to its mouth before it meets the sea. It shows how the river changes over its course.
- Upper course** - in the upper course, where the river starts, there is often an upland area. The river's load is large in the upper course, as it hasn't been broken down by erosion yet.
 - Lower course** - in the lower course, the land is a lot flatter. The river's load is the sediment, as erosion has broken down the rocks.

Transportation

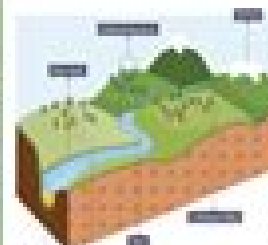

- The river picks up sediment and carries it downstream in different ways.
- Traction** - large, heavy pebbles are rolled along the river bed. This is most common near the source of a river, as here the bed is larger.
 - Solution** - particles are dissolved along the river bed, most commonly near the source.
 - Suspension** - lighter sediment is suspended (carried) within the water, most commonly near the mouth of the river.
 - Solution** - the transport of dissolved chemicals. The water along the river dissolves in the presence of soluble rocks.

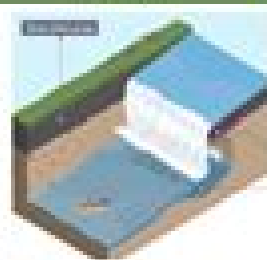

Deposition

- When the river loses energy, it drops any of the material it has been carrying. This is known as **deposition**.
- Point bar** - where the river is depositing material.
 - Headcut** - where the river is depositing material.
 - Point bar** - where the river is depositing material.

Landforms

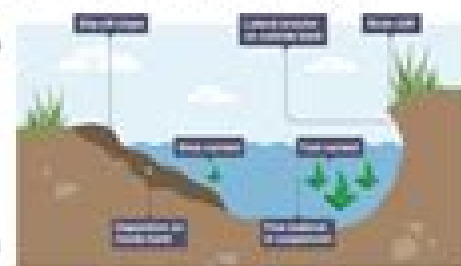

- Meandering types** in the upper course there is more vertical erosion. The river cuts down into the valley. If there are areas of hard rock which are harder to erode, the river will bend around it. This creates meandering spurs of land which are known as **point bars**.

- A waterfall** is a sudden drop along the river course. It forms when there are horizontal bands of resistant rock (hard rock) positioned near together, less resistant rock (soft rock) below.
- The soft rock is eroded faster than the hard rock and this creates a dip.
 - As erosion continues, the hard rock is undercut forming an overhang.
 - Attrition and hydraulic action make it create a plunge pool.
 - Over time the gap widens, increasing the size of the overhang until the hard rock is no longer supported and it collapses.
 - The process continues and the waterfall retreats upstream.
 - A steep-sided valley is left where the waterfall once was. This is called a **gorge**.

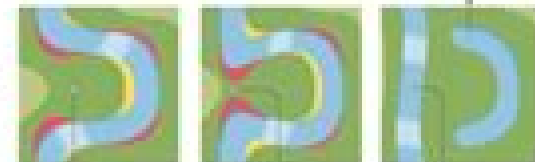

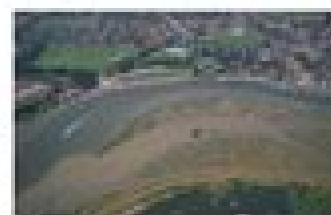

Erosional & Depositional Landforms

- As the river moves to the middle course, it gains more water and therefore more energy. Lateral erosion starts to widen the river. When the river flows over flatter land they develop large **floodplains**.
- As a river goes around a bend, most of the water is pushed towards the outside. The water moves faster and therefore increased erosion (through hydraulic action and abrasion).
 - The lateral erosion on the outside bank causes undercutting of the bank to form a **river cliff**.
 - Water on the river bank is slower, causing the water to slow down and deposit the eroded material, creating a gentle slope of sand and shingle.
 - The build-up of deposited sediment is known as a **point bar** (or sometimes **river beach**).

- Colluviation** Due to erosion on the outside of a bend and deposition on the inside, the shape of a riverbed will change over a period of time. Erosion widens the river bed at the bend and as the process continues, the meanders move closer together. When there is a very high discharge (usually during a flood), the river cuts across the neck, taking a less straight and shorter route. Deposition will occur to cut off the original meander, leaving a horseshoe-shaped oxbow lake.

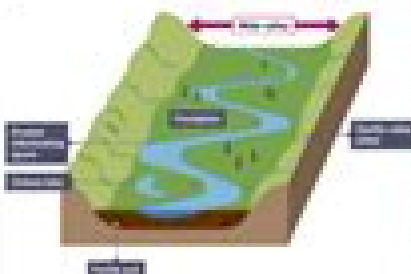

- An oxbow lake** is where the river meets the sea. The river flows in a loop and when the sea reaches the volume of the water in the estuary is less reduced. When there is too much water, the river deposits all its silt and mud which are an important habitat for wildlife.

Area of deposition Area of erosion

Erosional Landforms
by moving features are also found in the upper course of the river

Depositional Landforms
by moving features are also found in the lower course of the river

- A floodplain** is an area of land which is covered in water when a river bursts its banks.

- Floodplains form due to both erosion and deposition. Erosion removes any meandering spurs, creating a wide, flat area on either side of the river. During a flood, material being carried by the river is deposited (as the river loses its speed and energy to transport material). Over time, the layers of the floodplain increase as material is deposited on either side of the river. Floodplains are often agricultural land, as the area is very fertile because it's made up of silt and mud (deposited off the river during a flood). The floodplain is often a wide, flat area around the river to increase the risk of flooding.

- Levees** occur in the lower course of a river when there is an increase in the volume of water flowing downstream and flooding occurs.
- Sediment that has been eroded further upstream is transported downstream.
 - When the river flows, the sediment spreads out across the floodplain.
 - When a flood occurs, the river flows faster. The largest material is deposited first on the sides of the river banks and smaller material further away.
 - After many floods, the sediment builds up to increase the height of the river banks, meaning that the channel can carry more water (a greater discharge) and flooding is less likely to occur in the future.
