Marco Iosa,Nadia Dominici,Federica Tamburella,Leonardo Gizzi,2015-07-29 Locomotion involves many different muscles and

the need of controlling several degrees of freedom Despite the Central Nervous System can finely control the contraction of

individual muscles emerging evidences indicate that strategies for the reduction of the complexity of movement and for

compensating the sensorimotor delays may be adopted Experimental evidences in animal and lately human model led to the

concept of a central pattern generator CPG which suggests that circuitry within the distal part of CNS i e spinal cord can

generate the basic locomotor patterns even in the absence of sensory information Different studies pointed out the role of

CPG in the control of locomotion as well as others investigated the neuroplasticity of CPG allowing for gait recovery after

spinal cord lesion Literature was also focused on muscle synergies i e the combination of locomotor functional modules

implemented in neuronal networks of the spinal cord generating specific motor output by imposing a specific timing

structure and appropriate weightings to muscle activations Despite the great interest that this approach generated in the last

years in the Scientific Community large areas of investigations remain available for further improvement e g the influence of

afferent feedback and environmental constrains for both experimental and simulated models However also supraspinal

structures are involved during locomotion and it has been shown that they are responsible for initiating and modifying the

features of this basic rhythm for stabilising the upright walking and for coordinating movements in a dynamic changing

environment Furthermore specific damages into spinal and supraspinal structures result in specific alterations of human

locomotion as evident in subjects with brain injuries such as stroke brain trauma or people with cerebral palsy in people with death of dopaminergic neurons in the substantia nigra due to Parkinson's disease or in subjects with cerebellar dysfunctions such as patients with ataxia The role of cerebellum during locomotion has been shown to be related to coordination and adaptation of movements Cerebellum is the structure of CNS where are conceivably located the internal models that are neural representations miming meaningful aspects of our body such as input output characteristics of sensorimotor system Internal model control has been shown to be at the basis of motor strategies for compensating delays or lacks in sensorimotor feedbacks and some aspects of locomotion need predictive internal control especially for improving gait dynamic stability for avoiding obstacles or when sensory feedback is altered or lacking Furthermore despite internal model concepts are widespread in neuroscience and neurocognitive science neurorehabilitation paid far too little attention to the potential role of internal model control on gait recovery Many important scientists have contributed to this Research Topic with original studies computational studies and review articles focused on neural circuits and internal models involved in the control of human locomotion aiming at understanding the role played in control of locomotion of different neural circuits located at brain cerebellum and spinal cord levels *Advances in Biomedical and Molecular Neuroscience* Robert J.
