

BACKGROUND

1. What test can be used to determine whether a patient has an infectious or autoimmune disease?

The interaction of antigen and antibody outside the body—in the laboratory—can be used to determine if a patient has an infectious or an autoimmune disease.

2. What does a positive result indicate?

A positive result indicates that the antibody is there and implies that the person has encountered a particular disease.

3. The watery fluid of the blood is called serum.

4. What is allowed to react with the target antigen?

A portion of serum possibly containing the antibody is allowed to react with the target antigen.

5. Detection is possible when a second antibody is added.

6. Once isolated, the secondary antibody can be chemically linked to a system that can produce a detectable signal.

7. What is the signaling system?

The signaling system consists of an enzyme attached to the second antibody.

8. What happens when the appropriate chemical (substrate) is added?

The enzyme converts it to a colored substance that can be measured.

9. How is the test quantified?

This test quantifies how much enzyme is present by the amount of color produced. The more enzyme present, the more secondary antibody must be attached.

10. What does the amount of color reflect?

Because the first antibody binds to antigen, the more antigen that is accessible, the more first antibody will be retained. The measure of color, therefore, reflects the amount of antigen initially present.
