

## GEOGRAPHICAL AND SOCIAL VARIATIONS IN THE INCIDENCE OF NOTIFIED POLIOMYELITIS

BY

B. BENJAMIN and W. P. D. LOGAN

*From the General Register Office, London*

The natural history of poliomyelitis is not yet completely written. Although the clinical features of this disease have been recognized for more than a century, problems of management still give rise to controversy, and in spite of recurring outbreaks of widespread and dramatic character many enigmatic features of epidemiology remain to be explained. The outbreaks come without presage, reaching dimensions which cannot be forecast, and burning themselves out almost completely uncontrolled. While in the laboratory the search for prophylactic measures continues, there remains in the field a need for that combination of observation and hypothesis which may add to the accumulated epidemiological knowledge and consequently may add if even slightly to the state of preparedness of local health services. To this pattern, and in succession to an earlier review (Logan, 1952), the present study belongs.

If it were found that poliomyelitis reached epidemic prevalence invariably after a particular series of movements of attack rates or that the disease selected particular sections of the community or parts of the country, this would enable us to predict the commencement and spread of outbreaks, thus enabling clinical services to be mobilized on an adequate scale.

### UNEVEN PREVALENCE IN DIFFERENT AREAS

It is known that in individual outbreaks, even in urban areas, some localities may escape epidemic prevalence, for reasons which are not apparent, and also that areas which suffer high incidence in one epidemic may have a lower than average incidence in the next, perhaps by some carry-over of the herd immunity gained in the earlier outbreak (Breen and Benjamin, 1950). These two effects, independent

geographical variation and correlation between one local outbreak and the next, operate together; jointly they produce in any one outbreak considerable unevenness in geographical spread. In order to remove this second effect, carry-over of a higher level of immunity from the close of one epidemic to the onset of the next, it is necessary to average the prevalence over several epidemics. The question then remains whether the residual geographical variation in epidemicity is a matter of chance and a feature which will also disappear over a further period as individual localities experience their proportionate share of the total prevalence in due course.

Table I (overleaf) shows the result of averaging the years 1947-50: three years of severe epidemic prevalence and one year (1948) with comparatively few cases. In this Table the actual uncorrected\* notifications are compared with those "expected" if the England and Wales total notifications were distributed in proportion to the local population, i.e. if every area suffered the same attack rate. Looking first at each region as a whole, we find that prevalence was significantly† below average in the Northern, North Western, and Eastern Regions, and in Wales, and that it was significantly above average in the Midland, London and South Eastern, Southern, and South Western Regions.

In the remaining regions the differences between actual and expected notifications were not statistically significant. The significant differences are too large to be accounted for by the fact that (to be consistent with Table V) uncorrected notifications

\*Uncorrected notifications are the original notifications made to local Medical Officers of Health and transmitted to the General Register Office weekly; corrected notifications are the final notifications returned by the Medical Officer of Health quarterly, after taking account of corrections of diagnoses during the period.

†The criterion has been twice the standard error of the "expected".
