

to maintain a comfortable environment inside the house. By analyzing the heat transfer and air flow, we learn what heat transfer (and air flow) is required for the house to be a comfortable place. A thermodynamic analysis will tell us the conditions needed to maintain the temperature and relative humidity, and that analysis will tell us the size of the fan required to push the air in, the conditioner and the duct needed to distribute the cooled air throughout the house.

Perhaps we want to focus on the air conditioner itself. Figure 1.2 is a schematic of two heat exchangers, a compressor, and a valve. A thermodynamic analysis would tell us how much energy is required to maintain a desired amount of cooling. A heat transfer analysis would tell us the size of the heat exchangers. The fluid dynamics analysis would tell us the pressure drop across the compressor and the ducts, as well as the required compressor power.

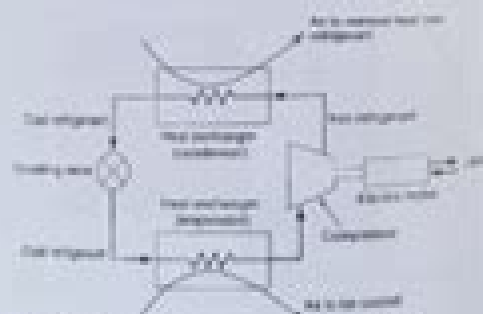

FIGURE 1.2 Schematic of a vapor-compression refrigeration cycle.

FIGURE 1.3 Schematic of a building with a cooling system.

It is a simple task, however, to analyze a cooling system with a compressor (Figure 1.3). The compressor design and power supply must be selected so that the refrigerant of the system is not compressed. This requires a cooling approach to be known so that the compressor can be selected. A thermodynamic analysis of each room, the ducts, and the compressor will tell us the amount of energy that must be provided to maintain the desired conditions. The design of the air conditioning system will be selected so that the refrigerant of the air conditioning system will not be compressed. This is a simple task, however, to analyze a cooling system with a compressor. This requires a cooling approach to be known so that the compressor can be selected. A thermodynamic analysis of each room, the ducts, and the compressor will tell us the amount of energy that must be provided to maintain the desired conditions.

1.2 THERMAL AND FLUID SYSTEMS ANALYSIS AND ENGINEERING

Additional examples, similar to those given in the previous section, can be given of large industrial systems (e.g., power plants, oil refineries, chemical processing plants) and related processes (e.g., heat treatment of metals). Heat exchangers that would transfer heat from a process to a cooling water stream, and fluid dynamics are all needed in many design tasks. It is the engineer's job to know these disciplines that is required for thermal and fluid systems analysis of many systems.

Whether the engineer is given an assignment to design a new device or to redesign an existing process or to predict the performance of a device, the objective of the design process must be very clear. Subsequent, which aspect of the device, process, or system is to be designed must be well defined. A systematic approach to the design process is needed. Figure 1.4 shows a flow diagram of the design process. The design process typically takes three steps: defining the problem, analyzing the problem, and synthesizing a design. The design process is a physical system (e.g., the design of a machine, the design of a process, the design of a system). The design process is a physical system, and, as such, it must be described by a mathematical model. The actual physical system may be so complex that it is impossible to fully describe each part within the system. However, we require that there be a model, a synthesis, or synthesis that we can use to predict the behavior of the system sufficiently so that it can be designed. Once a physical model is developed, then physical laws that govern the process (e.g., a force, momentum, mass, or energy balance) are used to create the
