Human lung capacity is an issue made possible by pleural cavity - space surrounding internal organs. One way to measure volume of pleural cavity is spirometer. Lung capacity can also be measured using a balloon. This data provides very precise measurement method without using a spirometer though.

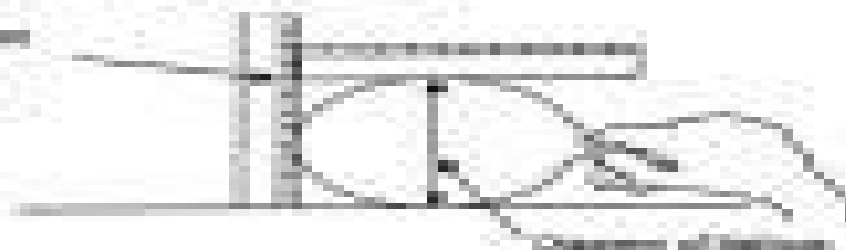

Several different lung volume measurements can be made:

1. Tidal capacity is the largest possible amount of air that can be inhaled after breathing a normal breath.
2. Expiratory reserve is the amount of air that can be inhaled in the lungs after exhaling normally (it is the portion that remains inhaled air).
3. Total volume is the amount of air taken in or expelled during normal breathing.

## Part A: Balloon Method

1. Measure the balloon circumference.
2. Take an average breath in (inhale). Then submerge the air into water in the balloon and push the balloon down to the bottom of the water.
3. Measure and record the diameter of the balloon in centimeters (see Data Table below). The difference between the top and bottom water measurements is.

Record measurement where the height of the balloon equals the water value (note the balloon water level). This is the balloon's diameter.

4. Calculate the balloon and diameter water level. Record the diameter of the balloon in your Data Table.
5. Repeat steps 1-4 three times (LAST PLACE where possible). Results calculated goes with the diameter.
