Geomorphology: The Great Sand Dunes National Park

Declared a national monument by the National Parks and Preserve Act of 2000, the Great Sand Dunes are the largest dunes in North America, rising a staggering 750 feet; the dunes are located at the base of an alcove in the Sangre de Cristo Mountain Range in Colorado. For geographical clarity, it is important to note that both the San Juan and Sangre de Cristo Mountain Ranges are part of the larger Rocky Mountains and are separated by the San Luis Valley.

Building the Great Sand Dunes

While it is commonly accepted that the Great Sand Dunes are a young landform, a precise age has not been determined. "U.S. Geological Survey geologists estimate that the dunes are between a couple of thousand years and 12,000 years old...."¹ What is lucidly understood, however, is the process and structure by which the sand dunes are created and maintained.

Building the Great Sand Dunes National Park requires four predominant factors—plentiful loose sediment deposits, strong winds, a permanent sand trap structure, and a method by which to control the expansion or migration of the dunes. Loose sediment in the form of sand, silt, and gravel exists in abundance across the floor of the San Luis Valley; "[t]he sand is blown by prevailing southwesterly wind from alluvial sediments of the San Luis Valley. Sand mineralogy indicates that much of the sediment was derived from volcanic rocks of the San Juan Mountains, transported by the Rio Grande, and deposited in the river's huge alluvial fan on the western side of the valley."² Sand carried by the wind is directed by the Sangre de Cristo Mountains north and funneled into a naturally occurring sand trap—an alcove in the mountain
