What did you learn?

What?

Antigen-antibody reactions in human transfusions are the basis used to select compatible human blood groups, where compatibility is the ability to transfuse blood successfully to the body, or vice versa, to prevent damage and death to all organs. In transfusions, bloods and blood cells have antigens for being recognized as self or foreign. Selfing bloods are safe and cells with the same blood type are selfing.

Human Blood Analysis M. K.

Bhasin, Surinder Nath, V. N. Sehgal, 2007 Blood is a biological material and is the most common evidence found in all types of forensic investigations. There are two major areas of investigation: Testing for biological evidence of kinship in civil cases and characterization of blood stains in criminal cases. Blood group typing is still the most commonly used immunological method employed by forensic serologists for the individualization of blood. Certain enzymes and blood proteins exist in multiple genetically different forms. In case of enzymes, these forms are known as isoenzymes. The discovery of HLA polymorphism not only involves the variable alleles in individual loci but also the haplotypes of neighboring linked loci, which increases the discrimination potential for individualization and association of some HLA antigens with particular ethnic groups, thereby making them important from the forensic point of view. The molecular biology has provided more reliable techniques of DNA fingerprinting, which has revolutionized the forensic analysis of blood evidence in crime investigation, and today it is possible to provide valuable information in cases where scarce or a degraded amount of crime scene material could have been a limiting factor. Population studies and generation of DNA databases and quality systems are further advancements in the forensic investigation of blood evidence. The blood analysis proves useful for the forensic serologist in establishing the reliability of the results in any court of law.
