

que se dice explícitamente.

2) Política por defecto DENEGAR: todo está denegado, y solo se permitirá pasar por el firewall aquello que se permite explícitamente.

Como es obvio imaginar, la primera política facilita mucho la gestión del firewall, ya que simplemente nos tenemos que preocupar de proteger aquellos puertos o direcciones que realmente que nos interesen, el resto no importa tanto y se deja pasar. Por ejemplo, si queremos proteger una máquina local, podemos hacer un `netstat -ln` o `netstat -ptn` (para el grupo LISTEN), saber qué puertos están abiertos, poner reglas para proteger esos puertos y ya está. ¿Pero qué vamos a proteger los puertos que realmente nunca se va a abrir?

El único problema que podemos tener es que no controlaremos que se lo que está abierto, o que en un momento dado se instale un software nuevo que abra un puerto determinado, o que no sepamos qué determinados puertos ICMP son peligrosos. Si la política por defecto es ACCEPTAR y no se protege explícitamente, nos lo estamos jugando sin parar.

En cambio, si la política por defecto es DENEGAR, a no ser que lo permitamos explícitamente, el firewall se convierte en un auténtico **BLINDO** indomable. El problema es que es mucho más difícil preparar un firewall así, y hay que tener muy claro cómo funciona el sistema (con iptables o el que sea) y que en lo que se tiene que abrir sin caer en la tentación de empezar a meter reglas `reset` permitivas.

Una configuración de firewall es la recomendada, aunque no es aconsejable usarla si no se domina mínimamente el sistema. Uno de los objetivos principales de este documento es mostrar la forma de crear este tipo de firewall.

IMPORTANTE

El orden en el que se ponen las reglas de firewall es determinante. Normalmente cuando hay que decidir que se hace con un paquete se va comparando con cada regla del firewall hasta que se encuentra una que le afecta (match), y se hace lo que dice esta regla (aceptar o denegar), después de eso **NO SE MUEVE MÁS LA REGLA** para ese paquete. ¿Cuál es el peligro? Si ponemos reglas muy permisivas como las primeras del firewall, puede que las siguientes no se apliquen y se abran de más.

2. Qué es iptables

Iptables es un sistema de firewall vinculado al kernel de linux que se ha extendido sucesivamente a partir del kernel 2.4 de este sistema operativo. Al igual que el anterior sistema iptulipes, un firewall de iptables no es como un servidor que se inicia/para o detiene/para o que se pueda caer por un error del programador/usuario es una pequeña máquina, ha tenido alguna vulnerabilidad que permitir DDoS, pero nunca tendrá tanto peligro como las aplicaciones que escuchan en determinado puerto TCP: iptables está integrado con el kernel, es parte del sistema operativo. ¿Cómo se pone en marcha? Realmente lo que se hace es aplicar reglas. Para ello se ejecuta el comando `iptables`, con el que añadimos, borramos, o cambiamos reglas. Por ello un firewall de iptables es en sí un simple script de shell en el que se van ejecutando las reglas de firewall.

Nótese, bueno, para los más perezos e incapelitosos. Vale, se puede implementar un script de inicio de `/etc/rc.d/init.d` (o `/etc/init.d`) con el que hagamos que iptables se "inicie o pare" como un servicio más. Lo podemos hacer nosotros o es probable que venga en la distribución (como en muchos por ejemplo). También se pueden salvar las reglas aplicadas con el comando `iptables-save` en un fichero y gestionar ese fichero con una aplicación o `firewall-cmd` desde la X o desde webmin.

Vale, tenemos una máquina local con soporte para iptables, tiene reglas aplicadas y empieza a llegar/abrir/pasar paquetes. No nos hemos olvidado de contar también de qué hay, qué direcciones ip tiene la máquina y sabemos si el paquete entra o sale. Las reglas de firewall están a nivel de kernel, y el kernel lo que le llega es un paquete (paquetes, en plural) :) y tiene que decidir que hacer con él. El kernel lo que hace es, dependiendo si el paquete es para la propia máquina o para otra máquina, consultan las reglas de firewall y decide que hacer con el paquete según manda el firewall. Este es el camino que seguirá un paquete en el kernel:
