Daniel Benjamin Cortes,2015 Female meiosis in most metazoans facilitates the creating of a single haploid oocyte from an original diploid precursor with replicated chromosomes In order to promote accurate retention of only a single set of each

homologous chromosome female meiosis orchestrates a complex series of events that result in the placement of a small acentrosomal meiotic spindle in a perpendicular orientation adjacent to the cortex in both meiosis I and meiosis II. By placing the spindle perpendicular to the cortex along its major axis prior to anaphase, oocytes ensure that each division retains a single copy of each homolog in meiosis I or sister chromatid in meiosis II. Defects in the processes of meiosis can result in chromosome missegregation which induces aneuploidy. One specific form of aneuploidy wherein three copies of each chromosome are present, trisomy, is of special importance due to its prevalence in human infertility and due to the presence of viable trisomic humans with developmental disorders: Down Syndrome, Klinefelter, etc. In humans, trisomy is believed to arise mostly through errors in female meiosis, highlighting the error-prone nature of female meiosis. Several mechanisms known to promote trisomy occur during female meiosis and in the mitotic divisions thereafter, usually as a result of meiotic errors. Herein, we highlighted some of these known mechanisms and their consequences in human, mouse, and *C. elegans*. Despite the breadth of knowledge about defects of female meiosis and early embryonic development, however, little is known about any mechanisms that might rescue trisomy *in vivo*. Case studies of triploX and Down Syndrome reproductive humans show fewer than expected trisomic progeny based on traditional Mendelian segregation. Using triploX strains of the nematode *Caenorhabditis elegans* as well as some mutants with unpaired chromosomes, we investigated whether female meiosis and the sequential mitotic divisions bear mechanisms that reduce the incidence of trisomy or more generally the incidence of unpaired chromosome inheritance. In this work, we show evidence that three distinct mechanisms act through meiosis and early mitosis in *C. elegans* embryos to selectively expel unpaired chromosomes. First, we observed a measurable reduction in inheritance of unpaired chromosomes occurring during anaphase of meiosis I that is dependent on the active placement of the meiotic contractile ring. Next, we provide evidence for a mechanism that relied on the rotation of meiotic spindles from their metaphase orientation parallel to the cortex into their anaphase orientation perpendicular to the cortex. In that work, we used ASPM, a marker of spindle poles, as being consistently asymmetric on spindle poles in a way that predicted spindle orientation following rotation. Unpaired chromosomes in a triploX strain frequently associated with an ASPM-enriched pole which ended up at the cortex after rotation. Finally, we provide preliminary evidence for a mechanism that provides further correction after meiosis has completed. The incidence of trisomy was further reduced by mitotic correction in the first few divisions of embryonic development, producing a population of mosaic embryos which were partially returned to disomy. Together, these data support a model where trisomy is detected by meiotic and mitotic embryos and a series of mechanisms activate in order to reduce the chances of excess chromosome inheritance.
