

1. Complete these definitions or ideas that are central to understanding the Hardy-Weinberg theorem.
 - a. Population: A group of individuals of the same species that live in the same area and interbreed to produce fertile offspring
 - b. Gene pool: The total aggregate of all the alleles for all of the loci for all of the individuals in a population
 - c. Genetic drift:
 - d. Allele frequency:
 - e. Genotype:
 - f. Phenotype:
2. Suppose that there is a population of plants that have flower color that is controlled by one gene. Where R is completely dominant and codes for a red flower over r is recessive and encodes a white flower.

A flower that is heterozygous will have a genotype of Rr and a phenotype of RED
3. Consider the example of the medium ground finch (*Geospiza fortis*), a seed-eating bird that lives on the Galápagos Islands. In 1977, the *G. spiza* population endured a long period of drought. Of 1200 birds, only 180 survived. The surviving finches had larger, deeper beaks than the finches that died. Soft, small seeds were in short supply during the drought. Large, hard seeds were more abundant. Finches with large, deep beaks could crack the large seeds and thus were able to survive the food shortage during the drought.

A common misconception is that individual organisms evolve over their lifetimes. However, evolution is the changes in the population overtime.

 - a. Natural selection does act on individuals. Explain how individuals did not evolve and natural selection acted on the individual finches in the example above.

Individual finches did not evolve. Each bird had a beak of a particular size, which did not grow larger during the drought.
 - b. Explain how the finch population evolved from one generation to the next in the example above.

The proportion of birds with large beaks in the population increased from generation to generation because birds with large beaks were better able to survive the drought and reproduce successfully
4. In this chapter we discuss changes in allele frequencies in a population from one generation to the next. This type of evolution is called MICRO EVOLUTION
5. There are three (3) mechanisms that can change allele frequencies in a population. State them below.
 - a. Natural Selection
 - b. Genetic Drift
 - c. Gene flow

Urban Evolutionary Biology Marta Szulkin, Jason Munshi-South, Anne Charmantier, 2020 Cities occupy about 3 per cent of the Earth's habitable land area and are home to one out of two humans worldwide both estimates are predicted to grow Urban space is thus becoming an important novel ecological niche for humans and wildlife alike Building on knowledge gathered by urban ecologists during the last half century evidence of evolutionary responses to urbanization has rapidly emerged Urban evolutionary biology is a nascent yet fast growing field of research and a fascinating testing ground for evolutionary biologists worldwide Urbanization offers a great range of opportunities to examine evolutionary processes because of the radically altered and easily quantifiable urban habitat and the large number of cities worldwide enabling rigorous replicated tests of evolutionary hypotheses Urban populations are increasingly exhibiting both neutral and adaptive evolutionary changes at levels ranging from genotypes to phenotypes The novelty of urban evolutionary biology is that these changes are driven by the cities we have built including effects of infrastructure pollution and social characteristics of our urban neighbourhoods It will thereby enrich the field of evolutionary biology with emergent yet incredibly potent new research themes where the urban habitat is key In a series of sixteen chapters written by leading evolutionary biologists working on urban drivers of evolution Urban Evolutionary Biology is the first academic book in the field It synthesizes current knowledge on evolutionary processes occurring literally on our doorstep across the globe and in each city independently Provided by publisher
