## 3. Evidence from Comparative Anatomy

A comparative study of the bone structures and body systems of animals from different phyla reveals a great deal of similarity. There are three different forms of evidence that arise from comparative anatomy.

Homologous Structures	Analogous Structures	Vestigial Structures
• Anatomical structures that look alike although used for very different purposes.	• Anatomical structures that share a common function, but not structure.	• Anatomical structures inherited from ancestors but have lost much of their original function.
• For example, the flipper of a whale, the arm of a human, and the wing of a bird have similar bone structures, indicating that they have the same evolutionary origin, even though they are used for different movements.	• For example, the wings of birds, bees, and bats show anatomical and functional similarities as they have evolved to help with flight. However, they have very different evolutionary origins.	• For example, dolphins have rudimentary hipbones which are not used in their aquatic life. Dolphins have retained these structures because they do not affect the fitness of dolphins, so natural selection has not eliminated them.

Homologous Structures – Mammalian Limbs

Analogous Structures – Limbs for Flight

4. Evidence from Comparative Embryology

Embryology is the study of developing forms in embryos. Specifically, a comparative study of seemingly unrelated species of vertebrates show similar evolutionary origins.

In other words, the **early developmental stages of many vertebrate animals look very similar.** Recent studies have shown that embryonic cells of very different species of vertebrates develop in the same order and in the same pattern, and go on to produce homologous structures. These results indicate that vertebrate organisms have evolved from a common ancestor.
