

$$\chi^2 = 5.759995408$$

$$Df = (rows - 1)(columns - 1)$$

$$Df = (2 - 1)(2 - 1)$$

$$Df = 1$$

The χ^2 critical value at 5% significance with 1 degree of freedom is 3.841. As the χ^2 value is greater than the critical value, $5.760 > 3.841$, the null hypothesis is rejected and SAT score is assumed dependent from family income.

Discussion/Validity

Limitations

Throughout the investigation between the correlation of SAT scores and family income, various limitations may have affected the outcome of the results.

One limitation of the data collected could be that it only reflects on the people who filled in the family income section before signing up for the SAT. There is no evidence that the data reflects everyone who has taken the SAT score as there may be people who did not fill that section.

Another limitation could be that not everyone in the world decide to take the SAT, people who cannot afford it or take alternative tests are being neglected. Also the data does not confirm of how many SAT takers are being considered. The data can be proved insufficient and inaccurate for those reasons.

There is also a limitation in the data as it states income of "\$100,000 and above". That could mean that the data goes on unto family incomes of millions which is not proportionate to the other ranges of family income given. Due to this however, that piece of data was left out in the calculations.

Continuing, there might be a limitation to the recording of the data itself as SAT takers are to take a survey where they mention family income when signing up for SAT. This might cause a problem as many SAT takers, mostly in ages 15-17, do not know the actual income of their family therefore wrong data may be entered.

Then there could be a limitation to the data due to culture and race. The data does not mention culture and race which might affect the data as there might have
