Introduction

In examining the behavior of a simple pendulum (below) in a previous (possibly 290) lab, we made the simplifying assumption that, for small initial launch angles, the $\sin\theta$ can be approximated by θ itself.

This gave us a rather simple expression for the period of a simple pendulum, T , that depended on the physical parameters L (length of pendulum), and g (acceleration at the Earth's surface owing to gravity) but not m (the mass of the pendulum bob). The simple expression is arrived at by considering the "return torque" ($\tau = L \cdot mg \sin\theta$), on the oscillator and the inertia which causes it to overshoot equilibrium, in this case the moment of inertia $I = mL^2$. The simple expression is the equation of motion for the pendulum:

$$\ddot{\theta} + \frac{g}{L} \sin\theta = 0 \Rightarrow \ddot{\theta} + \frac{g}{L} \theta = 0 \quad (1)$$

This simple expression can be solved for the period of the pendulum in the usual way, by assuming that t is some periodic function in time such as $A\sin(\omega t + \phi)$, taking it's second derivative, substituting, and solving for ω . This equation constitutes a simple **model** for the pendulum motion, given ω , ϕ and A , we state the mass's position at a time t .

Some assumptions are built into our simple model for the period of a simple pendulum as we have conceived it. An explicit assumption is that the initial (or *launch*) angle of the pendulum, sometimes called its initial displacement, is small. Less than 20° to be more precise. There is
