**Molecular/ Cellular/
Developmental Biology**

Physiology

Ecology/ Evolutionary Biology

Overarching Principles:

Biological structures exist at all levels of organization, from molecules to ecosystems. A structure's physical and chemical characteristics influence its interactions with other structures, and therefore its function.

Natural selection leads to the evolution of structures that tend to increase fitness within the context of evolutionary, developmental, and environmental constraints.

The structure of a cell--its shape, membrane, organelles, cytoskeleton, and polarity--impacts its function.

Physiological functions are often compartmentalized into different cells, tissues, organs, and systems, which have structures that support specialized activities.

Natural selection has favored structures whose shape and composition contribute to their ecological function.

The three dimensional structure of a molecule and its subcellular localization impact its function, including the ability to catalyze reactions or interact with other molecules. Function can be regulated through reversible alterations of structure e.g. phosphorylation.

The size, shape, and physical properties of organs and organisms all affect function. The ratio of surface area to volume is particularly critical for structures that function in transport or exchange of materials and heat.

Competition, mutualism, and other interactions are mediated by each species' morphological, physiological, and behavioral traits.

The structure of molecules or organisms may be similar due to common ancestry or selection for similar function.

Structure constrains function in physiology; specialization for one function may limit a structure's ability to perform another function.
