*Regeneration with an External Burner* Kenneth Michael Follen, 2007 Abstract Particulate matter has been identified by health agencies as a health risk and suspected of causing acute and chronic damage to the pulmonary and cardiovascular systems Since diesel engines are well known for their soot production legislation has been adopted to regulate the release of particulate matter into the atmosphere As these emissions standards become increasingly stringent new methods of emission control become necessary Of the options currently available particulate filters appear to be the most promising solution to meet and exceed these emission standards Particulate traps have been shown to successfully filter out up to 90 % of particulate matter However as particulate traps filter particulate matter they become filled resulting in an increase in the

exhaust back pressure To alleviate this increase in pressure the filter must be regenerated i.e. the particulate matter must be ignited and burned away leaving a clean trap Of the current regeneration methods active regeneration via an external burner is one of the more robust methods The scope of this work is to design a fuel fired heater for the purpose of supplying sufficient quantities of heat to elevate the exhaust temperature to the point at which diesel particulate filter DPF regeneration will occur As a precursor to the design an in depth literature review on the current state of the art as well as calculations of the design
