Department of Housing and Urban Development,1971 Genetic Recombination Alan S. Waldman,2008-02-03 Genetic recombination in the broadest sense can be defined as any process in which DNA sequences interact and undergo a transfer of information producing new recombinant sequences that contain information from each of the original molecules All organisms have the ability to carry out recombination and this striking universality speaks to the essential role recombination plays in a variety of biological processes fundamentally important to the maintenance of life Such processes include DNA repair regulation of gene expression disease etiology meiotic chromosome segregation and evolution One important aspect of recombination is that it typically occurs only between sequences that display a high degree of sequence identity The stringent requirement for homology helps to ensure that under normal circumstances a cell is protected from deleterious rearrangements since a swap of genetic information between two nearly identical sequences is not expected to dramatically alter a genome Recombination between dissimilar sequences which does happen on occasion may have such harmful consequences as chromosomal translocations deletions or inversions For many organisms it is also important that recombination rates are not too high lest the genome become destabilized Curiously certain organisms such as the trypanosome parasite actually use a high rate of recombination at a particular locus in order to switch antigen expression continually and evade the host immune system
