

to maintain a comfortable environment inside the house. By analyzing the heat transfer and air flow, we learn what heat transfer (and air flow) is required for the house to be a comfortable place. A thermodynamic analysis will tell us the conditions needed to maintain the temperature and relative humidity, and that analysis will tell us the size of the fan required to push the air in, the conditioner and the ducts needed to distribute the cooled air throughout the house.

Perhaps we want to focus on the air conditioner itself. Figure 1.2 is a schematic of two heat exchangers, a compressor, and a valve. A thermodynamic analysis would tell us how much energy is required to maintain a desired amount of cooling. A heat transfer analysis would tell us the size of the heat exchangers. The fluid dynamics analysis would tell us the pressure drop across the compressor and the ducts, as well as the required compressor power.

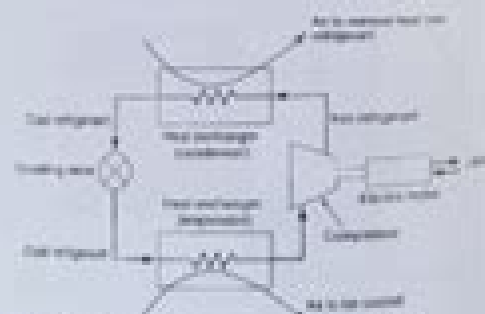

FIGURE 1.2 Schematic of a vapor-compression refrigeration cycle.

FIGURE 1.3 Schematic of a building showing heat transfer.

It is a simple task, however, a cooling system with a compressor (Figure 1.3). The compressor, the condenser, the evaporator, and the expansion valve must be selected so that the refrigerant of the system is not compressed. The condenser cooling approach is to have air through the condenser coils to remove unwanted heat. A thermodynamic analysis of each coil, the condenser, and the evaporator will tell us the amount of energy that must be removed from the condenser coils so that the temperature of the air entering the condenser coils will not exceed a given limit. That analysis will tell us what size coil design, fan, or other cooling equipment is needed to maintain the temperature of a fully compressed. That analysis will tell us the fan size needed to push air through the coils and then the air out of the condenser and out of the evaporator coils.

## 1.2 THERMAL AND FLUID SYSTEMS ANALYSIS AND ENGINEERING

Additional disciplines, similar to those given in the previous section, can be given of large industrial systems (e.g., power plants, oil refineries, chemical processing plants) and related processes (e.g., heat treatment of metals, food processing) that would illustrate how thermodynamics, heat transfer, and fluid dynamics are all needed in many design fields. It is the integrated use of these three disciplines that is required for rational and complete analysis of many systems.

Whether the objective is given an assignment to design a new device or modification to an existing process or to predict the performance of a device, the objective of the design process must be very clear. Subsequent, which aspect of the device, process, or system in which to focus must be well defined. A systematic approach to the design analysis is needed. Figure 1.4 shows a flow diagram of the design process. The design process typically takes three, analyzing and engineering a device from concept. We always begin with the physical system (e.g., the engine of a car). Then we model. The engineer's job is, first, to describe the physical system into a physical model and, second, to describe the physical model with a mathematical model. The actual physical system may be so complex that it is impossible to fully describe each part within process. However, we require that device as a model, a picture, or picture that we can use to describe and understand the system sufficiently so that it can be modeled. Once a physical model is developed, then physical laws that govern the process (e.g., a force, momentum, mass, or energy balance) are used to create the
