

Q.31: Describe the power of a lens.

Ans: **The Power of a Lens:**

Lenses are used to converge or diverge the incident light rays. The ability of a lens to refract the rays of light depends on its focal length. For example, a convex lens with a shorter focal length bends the light rays through a higher convergence by focusing them closer to the optical centre.

Similarly, a very short focal length of the concave lens will cause the light rays to diverge at higher angles away from the focal point. The degree of convergence or divergence of light rays attained by a lens expresses its refractive power.

Definition:

The power of a lens is defined as the reciprocal of its focal length, measured in meters inverse (m^{-1}).

The power is represented by the letter P. The power P of a lens of focal length f is given by

$$P = \frac{1}{\text{focal length}} \quad \text{or} \quad P = \frac{1}{f}$$

S.I Unit of the Power of a Lens:

The S.I unit of power of a lens is the 'diopter'. It is denoted by the letter D. The power of a lens whose focal length is

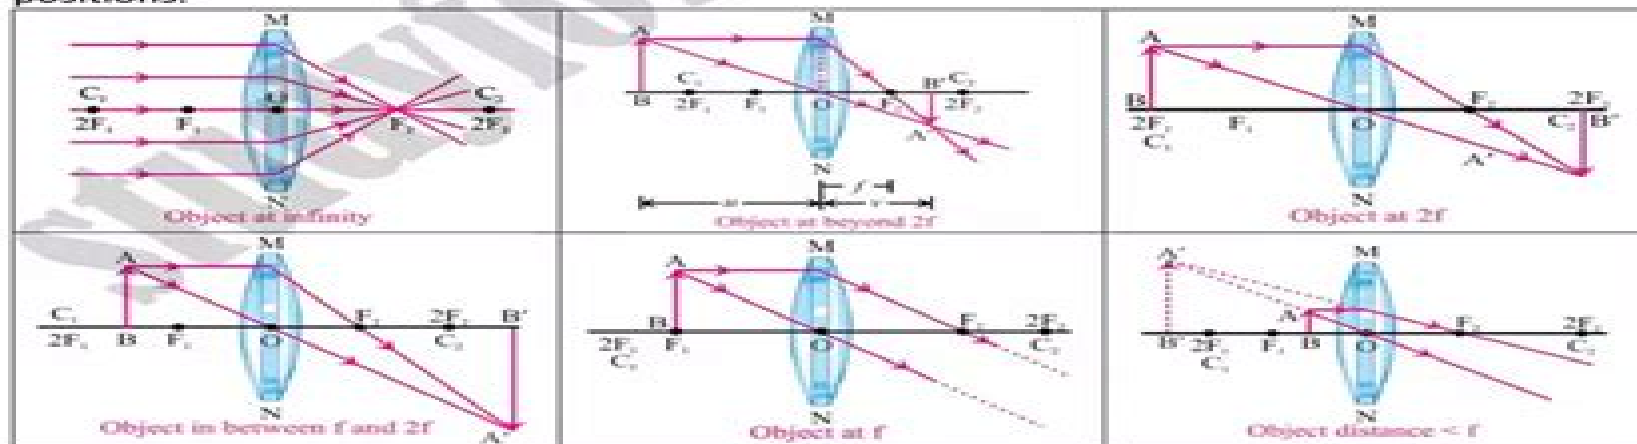

$$1\text{D} = 1\text{ m}^{-1}$$

It is always to be remembered that the power of a convex lens is positive, and that of concave lens is negative.

Q.32: How do images formed by lenses?

Ans: **Image Formation by Lenses:**

The ray diagrams illustrate the formation of images by a convex lens for various object positions.

Ray diagrams for the image formation by a convex lens

Geometric Optics for Surface Waves in Nonlinear Elasticity Jean-François Coulombel,Mark Williams,2020-04-03 This work is devoted to the analysis of high frequency solutions to the equations of nonlinear elasticity in a half space The authors consider surface waves or more precisely Rayleigh waves arising in the general class of isotropic hyperelastic models which includes in particular the Saint Venant Kirchhoff system Work has been done by a number of authors since the 1980s on the formulation and well posedness of a nonlinear evolution equation whose exact solution gives the leading term of an approximate Rayleigh wave solution to the underlying elasticity equations This evolution equation which is referred to as the amplitude equation is an integrodifferential equation of nonlocal Burgers type The authors begin by reviewing and providing some extensions of the theory of the amplitude equation The remainder of the paper is devoted to a rigorous proof in 2D that exact highly oscillatory

Rayleigh wave solutions u to the nonlinear elasticity equations exist on a fixed time interval independent of the wavelength and that the approximate Rayleigh wave solution provided by the analysis of the amplitude equation is indeed close in a precise sense to u on a time interval independent of This paper focuses mainly on the case of Rayleigh waves that are pulses which have profiles with continuous Fourier spectrum but the authors method applies equally well to the case of wavetrains whose Fourier spectrum is discrete
