Figure 8.2 Network of Figure 8.1 following the removal of the effects of V_{CC} , C_1 , and C_2 .

Figure 8.3 Substituting the r_e model into the network of Fig. 8.2.

The next step is to determine β , r_e , and r_o . The magnitude of β is typically obtained from a specification sheet or by direct measurement using a curve tracer or transistor testing instrument. The value of r_e must be determined from a dc analysis of the system, and the magnitude of r_o is typically obtained from the specification sheet or characteristics. Assuming that β , r_e , and r_o have been determined will result in the following equations for the important two-port characteristics of the system.

Z_i Figure 8.3 clearly reveals that

$$Z_i = R_B \parallel \beta r_e \quad \text{ohms} \quad (8.1)$$

For the majority of situations R_B is greater than βr_e by more than a factor of 10 (recall from the analysis of parallel elements that the total resistance of two parallel resistors is always less than the smallest and very close to the smallest if one is much larger than the other), permitting the following approximation:

$$Z_i \approx \beta r_e \quad R_B \gg \beta r_e \quad \text{ohms} \quad (8.2)$$

Z_o : Recall that the output impedance of any system is defined as the impedance Z_o determined when $V_i = 0$. For Fig. 8.3, when $V_i = 0$, $I_i = I_b = 0$, resulting in an open-circuit equivalence for the current source. The result is the configuration of Fig. 8.4.

$$Z_o = R_C \parallel r_o \quad \text{ohms} \quad (8.3)$$

If $r_o \approx 10 R_C$, the approximation $R_C \parallel r_o \approx R_C$ is frequently applied and

$$Z_o \approx R_C \quad r_o \gg 10 R_C \quad (8.4)$$
