1. This chemical energy is stored in the pyrophosphate bond, which is located between ATP's final two phosphate groups. When the cells require energy to perform any function, ATP cleaves the third phosphate group, releasing a significant amount of energy stored in the bond between the third and second phosphate groups. ATP can release and store energy by breaking and re-forming the bonds between its phosphate groups. Additionally, when a cell has energy available, it can store small amounts of it by adding phosphate groups to ADP to produce ATP.
2. Photosynthesis is the conversion of light energy to chemical energy in the form of sugars. Light energy drives the formation of glucose molecules as well as other sugar molecules. Chloroplasts, which contain chlorophyll, are located in the mesophyll cells of green plants. Green plants store the energy of sunlight as chemical energy in the bonds of carbohydrates.
3. The cell's metabolic reactions produce a constant supply of ATP. When cells demand more ATP, they can produce it as well. When the demand for ATP increases, the cell's metabolic reactions produce more ATP. The cell's metabolic reactions produce ATP as they break down glucose. The cell's metabolic reactions produce ATP as they break down glucose. The cell's metabolic reactions produce ATP as they break down glucose.
